

**1. Introduction.** This is  $\text{\TeX}$ , a document compiler intended to produce typesetting of high quality. The Pascal program that follows is the definition of  $\text{\TeX}82$ , a standard version of  $\text{\TeX}$  that is designed to be highly portable so that identical output will be obtainable on a great variety of computers.

The main purpose of the following program is to explain the algorithms of  $\text{\TeX}$  as clearly as possible. As a result, the program will not necessarily be very efficient when a particular Pascal compiler has translated it into a particular machine language. However, the program has been written so that it can be tuned to run efficiently in a wide variety of operating environments by making comparatively few changes. Such flexibility is possible because the documentation that follows is written in the **WEB** language, which is at a higher level than Pascal; the preprocessing step that converts **WEB** to Pascal is able to introduce most of the necessary refinements. Semi-automatic translation to other languages is also feasible, because the program below does not make extensive use of features that are peculiar to Pascal.

A large piece of software like  $\text{\TeX}$  has inherent complexity that cannot be reduced below a certain level of difficulty, although each individual part is fairly simple by itself. The **WEB** language is intended to make the algorithms as readable as possible, by reflecting the way the individual program pieces fit together and by providing the cross-references that connect different parts. Detailed comments about what is going on, and about why things were done in certain ways, have been liberally sprinkled throughout the program. These comments explain features of the implementation, but they rarely attempt to explain the  $\text{\TeX}$  language itself, since the reader is supposed to be familiar with *The  $\text{\TeX}$ book*.

2. The present implementation has a long ancestry, beginning in the summer of 1977, when Michael F. Plass and Frank M. Liang designed and coded a prototype based on some specifications that the author had made in May of that year. This original protoT<sub>E</sub>X included macro definitions and elementary manipulations on boxes and glue, but it did not have line-breaking, page-breaking, mathematical formulas, alignment routines, error recovery, or the present semantic nest; furthermore, it used character lists instead of token lists, so that a control sequence like `\halign` was represented by a list of seven characters. A complete version of T<sub>E</sub>X was designed and coded by the author in late 1977 and early 1978; that program, like its prototype, was written in the SAIL language, for which an excellent debugging system was available. Preliminary plans to convert the SAIL code into a form somewhat like the present “web” were developed by Luis Trabb Pardo and the author at the beginning of 1979, and a complete implementation was created by Ignacio A. Zabala in 1979 and 1980. The T<sub>E</sub>X82 program, which was written by the author during the latter part of 1981 and the early part of 1982, also incorporates ideas from the 1979 implementation of T<sub>E</sub>X in MESA that was written by Leonidas Guibas, Robert Sedgewick, and Douglas Wyatt at the Xerox Palo Alto Research Center. Several hundred refinements were introduced into T<sub>E</sub>X82 based on the experiences gained with the original implementations, so that essentially every part of the system has been substantially improved. After the appearance of “Version 0” in September 1982, this program benefited greatly from the comments of many other people, notably David R. Fuchs and Howard W. Trickey. A final revision in September 1989 extended the input character set to eight-bit codes and introduced the ability to hyphenate words from different languages, based on some ideas of Michael J. Ferguson.

No doubt there still is plenty of room for improvement, but the author is firmly committed to keeping T<sub>E</sub>X82 “frozen” from now on; stability and reliability are to be its main virtues.

On the other hand, the WEB description can be extended without changing the core of T<sub>E</sub>X82 itself, and the program has been designed so that such extensions are not extremely difficult to make. The *banner* string defined here should be changed whenever T<sub>E</sub>X undergoes any modifications, so that it will be clear which version of T<sub>E</sub>X might be the guilty party when a problem arises.

If this program is changed, the resulting system should not be called ‘T<sub>E</sub>X’; the official name ‘T<sub>E</sub>X’ by itself is reserved for software systems that are fully compatible with each other. A special test suite called the “TRIP test” is available for helping to determine whether a particular implementation deserves to be known as ‘T<sub>E</sub>X’ [cf. Stanford Computer Science report CS1027, November 1984].

MLT<sub>E</sub>X will add new primitives changing the behaviour of T<sub>E</sub>X. The *banner* string has to be changed. We do not change the *banner* string, but will output an additional line to make clear that this is a modified T<sub>E</sub>X version.

```

define TeX_banner_k ≡ ‘This_is_TeX,Version_3.1415926’ { printed when TEX starts }
define TeX_banner ≡ ‘This_is_TeX,Version_3.1415926’ { printed when TEX starts }
define pTeX_version_string ≡ ‘-p3.5’ { current pTEX version }
define pTeX_banner ≡ ‘This_is_pTeX,Version_3.14159265’, pTeX_version_string
define pTeX_banner_k ≡ pTeX_banner { printed when pTEX starts }
define banner ≡ pTeX_banner
define banner_k ≡ pTeX_banner_k

```

3. Different Pascals have slightly different conventions, and the present program expresses T<sub>E</sub>X in terms of the Pascal that was available to the author in 1982. Constructions that apply to this particular compiler, which we shall call Pascal-H, should help the reader see how to make an appropriate interface for other systems if necessary. (Pascal-H is Charles Hedrick’s modification of a compiler for the DECsystem-10 that was originally developed at the University of Hamburg; cf. *SOFTWARE—Practice & Experience* **6** (1976), 29–42. The T<sub>E</sub>X program below is intended to be adaptable, without extensive changes, to most other versions of Pascal, so it does not fully use the admirable features of Pascal-H. Indeed, a conscious effort has been made here to avoid using several idiosyncratic features of standard Pascal itself, so that most of the code can be translated mechanically into other high-level languages. For example, the ‘with’ and ‘new’ features are not used, nor are pointer types, set types, or enumerated scalar types; there are no ‘var’ parameters, except in the case of files; there are no tag fields on variant records; there are no assignments *real* ← *integer*; no procedures are declared local to other procedures.)

The portions of this program that involve system-dependent code, where changes might be necessary because of differences between Pascal compilers and/or differences between operating systems, can be identified by looking at the sections whose numbers are listed under ‘system dependencies’ in the index. Furthermore, the index entries for ‘dirty Pascal’ list all places where the restrictions of Pascal have not been followed perfectly, for one reason or another.

Incidentally, Pascal’s standard *round* function can be problematical, because it disagrees with the IEEE floating-point standard. Many implementors have therefore chosen to substitute their own home-grown rounding procedure.

4. The program begins with a normal Pascal program heading, whose components will be filled in later, using the conventions of WEB. For example, the portion of the program called ‘⟨Global variables 13⟩’ below will be replaced by a sequence of variable declarations that starts in §13 of this documentation. In this way, we are able to define each individual global variable when we are prepared to understand what it means; we do not have to define all of the globals at once. Cross references in §13, where it says “See also sections 20, 26, . . .,” also make it possible to look at the set of all global variables, if desired. Similar remarks apply to the other portions of the program heading.

```

define mtype ≡ t@&y@&p@&e { this is a WEB coding trick: }
format mtype ≡ type { ‘mtype’ will be equivalent to ‘type’ }
format type ≡ true { but ‘type’ will not be treated as a reserved word }

⟨Compiler directives 9⟩
program TEX; { all file names are defined dynamically }
const ⟨Constants in the outer block 11⟩
mtype ⟨Types in the outer block 18⟩
var ⟨Global variables 13⟩

procedure initialize; { this procedure gets things started properly }
  var ⟨Local variables for initialization 19⟩
  begin ⟨Initialize whatever TEX might access 8⟩
  end;

⟨Basic printing procedures 58⟩
⟨Error handling procedures 79⟩

```

5. The overall T<sub>E</sub>X program begins with the heading just shown, after which comes a bunch of procedure declarations and function declarations. Finally we will get to the main program, which begins with the comment ‘*start\_here*’. If you want to skip down to the main program now, you can look up ‘*start\_here*’ in the index. But the author suggests that the best way to understand this program is to follow pretty much the order of T<sub>E</sub>X’s components as they appear in the WEB description you are now reading, since the present ordering is intended to combine the advantages of the “bottom up” and “top down” approaches to the problem of understanding a somewhat complicated system.

6. For Web2c, labels are not declared in the main program, but we still have to declare the symbolic names.

```
define start_of_TEX = 1 { go here when TEX's variables are initialized }
define final_end = 9999 { this label marks the ending of the program }
```

7. Some of the code below is intended to be used only when diagnosing the strange behavior that sometimes occurs when TEX is being installed or when system wizards are fooling around with TEX without quite knowing what they are doing. Such code will not normally be compiled; it is delimited by the codewords '**debug** ... **gubed**', with apologies to people who wish to preserve the purity of English.

Similarly, there is some conditional code delimited by '**stat** ... **tats**' that is intended for use when statistics are to be kept about TEX's memory usage. The **stat** ... **tats** code also implements diagnostic information for `\tracingparagraphs` and `\tracingpages`.

```
define debug ≡ ifdef(`TEXMF_DEBUG`)
define gubed ≡ endif(`TEXMF_DEBUG`)
format debug ≡ begin
format gubed ≡ end

define stat ≡ ifdef(`STAT`)
define tats ≡ endif(`STAT`)
format stat ≡ begin
format tats ≡ end
```

8. This program has two important variations: (1) There is a long and slow version called INITEX, which does the extra calculations needed to initialize TEX's internal tables; and (2) there is a shorter and faster production version, which cuts the initialization to a bare minimum. Parts of the program that are needed in (1) but not in (2) are delimited by the codewords '**init** ... **tini**' for declarations and by the codewords '**Init** ... **Tini**' for executable code. This distinction is helpful for implementations where a run-time switch differentiates between the two versions of the program.

```
define init ≡ ifdef(`INITEX`)
define tini ≡ endif(`INITEX`)
define Init ≡
  init
  if ini_version then
    begin
define Tini ≡
  end ; tini
format Init ≡ begin
format Tini ≡ end
format init ≡ begin
format tini ≡ end
```

⟨ Initialize whatever TEX might access 8 ⟩ ≡

⟨ Set initial values of key variables 21 ⟩

**Init** ⟨ Initialize table entries (done by INITEX only) 170 ⟩ **Tini**

This code is used in section 4.

9. If the first character of a Pascal comment is a dollar sign, Pascal-H treats the comment as a list of “compiler directives” that will affect the translation of this program into machine language. The directives shown below specify full checking and inclusion of the Pascal debugger when T<sub>E</sub>X is being debugged, but they cause range checking and other redundant code to be eliminated when the production system is being generated. Arithmetic overflow will be detected in all cases.

```

⟨ Compiler directives 9 ⟩ ≡
  @{@&$C-, A+, D-@} { no range check, catch arithmetic overflow, no debug overhead }
  debug @{@&$C+, D+@} gubed { but turn everything on when debugging }

```

This code is used in section 4.

10. This T<sub>E</sub>X implementation conforms to the rules of the *Pascal User Manual* published by Jensen and Wirth in 1975, except where system-dependent code is necessary to make a useful system program, and except in another respect where such conformity would unnecessarily obscure the meaning and clutter up the code: We assume that **case** statements may include a default case that applies if no matching label is found. Thus, we shall use constructions like

```

case x of
  1: ⟨ code for x = 1 ⟩;
  3: ⟨ code for x = 3 ⟩;
  othercases ⟨ code for x ≠ 1 and x ≠ 3 ⟩
endcases

```

since most Pascal compilers have plugged this hole in the language by incorporating some sort of default mechanism. For example, the Pascal-H compiler allows ‘*others:*’ as a default label, and other Pascals allow syntaxes like ‘**else**’ or ‘**otherwise**’ or ‘*otherwise:*’, etc. The definitions of **othercases** and **endcases** should be changed to agree with local conventions. Note that no semicolon appears before **endcases** in this program, so the definition of **endcases** should include a semicolon if the compiler wants one. (Of course, if no default mechanism is available, the **case** statements of T<sub>E</sub>X will have to be laboriously extended by listing all remaining cases. People who are stuck with such Pascals have, in fact, done this, successfully but not happily!)

```

define othercases ≡ others: { default for cases not listed explicitly }
define endcases ≡ end { follows the default case in an extended case statement }
format othercases ≡ else
format endcases ≡ end

```

11. The following parameters can be changed at compile time to extend or reduce TEX's capacity. They may have different values in INITEX and in production versions of TEX.

```

define file_name_size ≡ maxint
define ssup_error_line = 255
define ssup_max_strings ≡ 2097151
      { Larger values than 65536 cause the arrays to consume much more memory. }
define ssup_trie_opcode ≡ 65535
define ssup_trie_size ≡ "3FFFFFF"
define ssup_hyph_size ≡ 65535 { Changing this requires changing (un)dumping! }
define iinf_hyphen_size ≡ 610 { Must be not less than hyph_prime! }
define max_font_max = 9000 { maximum number of internal fonts; this can be increased, but
      hash_size + max_font_max should not exceed 29000. }
define font_base = 0 { smallest internal font number; must be ≥ min_quarterword; do not change this
      without modifying the dynamic definition of the font arrays. }

```

(Constants in the outer block 11) ≡

```

hash_offset = 514; { smallest index in hash array, i.e., hash_base }
      { Use hash_offset = 0 for compilers which cannot decrement pointers. }
trie_op_size = 35111;
      { space for "opcodes" in the hyphenation patterns; best if relatively prime to 313, 361, and 1009. }
neg_trie_op_size = -35111; { for lower trie_op_hash array bound; must be equal to -trie_op_size. }
min_trie_op = 0; { first possible trie op code for any language }
max_trie_op = ssup_trie_opcode; { largest possible trie opcode for any language }
pool_name = TEXMF_POOL_NAME; { this is configurable, for the sake of ML-TEX }
      { string of length file_name_size; tells where the string pool appears }
engine_name = TEXMF_ENGINE_NAME; { the name of this engine }

inf_mem_bot = 0; sup_mem_bot = 1; inf_main_memory = 3000; sup_main_memory = 256000000;
inf_trie_size = 8000; sup_trie_size = ssup_trie_size; inf_max_strings = 3000;
sup_max_strings = ssup_max_strings; inf_strings_free = 100; sup_strings_free = sup_max_strings;
inf_buf_size = 500; sup_buf_size = 30000000; inf_nest_size = 40; sup_nest_size = 4000;
inf_max_in_open = 6; sup_max_in_open = 127; inf_param_size = 60; sup_param_size = 32767;
inf_save_size = 600; sup_save_size = 80000; inf_stack_size = 200; sup_stack_size = 30000;
inf_dvi_buf_size = 800; sup_dvi_buf_size = 65536; inf_font_mem_size = 20000;
sup_font_mem_size = 147483647; { integer-limited, so 2 could be prepended? }
sup_font_max = max_font_max; inf_font_max = 50; { could be smaller, but why? }
inf_pool_size = 32000; sup_pool_size = 40000000; inf_pool_free = 1000; sup_pool_free = sup_pool_size;
inf_string_vacancies = 8000; sup_string_vacancies = sup_pool_size - 23000;
sup_hash_extra = sup_max_strings; inf_hash_extra = 0; sup_hyph_size = ssup_hyph_size;
inf_hyph_size = iinf_hyphen_size; { Must be not less than hyph_prime! }
inf_expand_depth = 10; sup_expand_depth = 10000000;

```

This code is used in section 4.

**12.** Like the preceding parameters, the following quantities can be changed at compile time to extend or reduce T<sub>E</sub>X's capacity. But if they are changed, it is necessary to rerun the initialization program `INITEX` to generate new tables for the production T<sub>E</sub>X program. One can't simply make helter-skelter changes to the following constants, since certain rather complex initialization numbers are computed from them. They are defined here using `WEB` macros, instead of being put into Pascal's `const` list, in order to emphasize this distinction.

```
define hash_size = 15000 { maximum number of control sequences; it should be at most about
    (mem_max - mem_min)/10; see also font_max }
define hash_prime = 8501 { a prime number equal to about 85% of hash_size }
define hyph_prime = 607 { another prime for hashing \hyphenation exceptions; if you change this,
    you should also change iinf_hyphen_size. }
```

**13.** In case somebody has inadvertently made bad settings of the “constants,” T<sub>E</sub>X checks them using a global variable called `bad`.

This is the first of many sections of T<sub>E</sub>X where global variables are defined.

⟨Global variables 13⟩ ≡

```
bad: integer; { is some “constant” wrong? }
```

See also sections 20, 26, 31, 33, 40, 51, 55, 74, 77, 80, 97, 105, 116, 117, 118, 119, 125, 171, 179, 187, 219, 252, 259, 262, 277, 292, 303, 307, 310, 311, 314, 315, 316, 339, 354, 369, 375, 393, 398, 399, 421, 449, 458, 491, 500, 504, 523, 524, 531, 538, 543, 550, 560, 561, 566, 603, 606, 616, 627, 657, 658, 672, 695, 730, 735, 775, 781, 825, 832, 834, 836, 839, 844, 850, 858, 883, 903, 911, 916, 918, 932, 937, 954, 958, 961, 982, 991, 993, 1000, 1043, 1086, 1279, 1294, 1312, 1318, 1344, 1355, 1358, 1392, 1394, 1396, 1404, 1405, 1410, 1430, 1446, and 1449.

This code is used in section 4.

**14.** Later on we will say ‘`if mem_max ≥ max_halfword then bad ← 14`’, or something similar. (We can't do that until `max_halfword` has been defined.)

⟨Check the “constant” values for consistency 14⟩ ≡

```
bad ← 0;
if (half_error_line < 30) ∨ (half_error_line > error_line - 15) then bad ← 1;
if max_print_line < 60 then bad ← 2;
if dvi_buf_size mod 8 ≠ 0 then bad ← 3;
if mem_bot + 1100 > mem_top then bad ← 4;
if hash_prime > hash_size then bad ← 5;
if max_in_open ≥ 128 then bad ← 6;
if mem_top < 256 + 11 then bad ← 7; { we will want null_list > 255 }
```

See also sections 112, 296, 533, and 1262.

This code is used in section 1345.

**15.** Labels are given symbolic names by the following definitions, so that occasional **goto** statements will be meaningful. We insert the label *exit* just before the **end** of a procedure in which we have used the **return** statement defined below; the label *restart* is occasionally used at the very beginning of a procedure; and the label *reswitch* is occasionally used just prior to a **case** statement in which some cases change the conditions and we wish to branch to the newly applicable case. Loops that are set up with the **loop** construction defined below are commonly exited by going to *done* or to *found* or to *not\_found*, and they are sometimes repeated by going to *continue*. If two or more parts of a subroutine start differently but end up the same, the shared code may be gathered together at *common\_ending*.

Incidentally, this program never declares a label that isn't actually used, because some fussy Pascal compilers will complain about redundant labels.

```

define exit = 10  { go here to leave a procedure }
define restart = 20 { go here to start a procedure again }
define reswitch = 21 { go here to start a case statement again }
define continue = 22 { go here to resume a loop }
define done = 30  { go here to exit a loop }
define done1 = 31 { like done, when there is more than one loop }
define done2 = 32 { for exiting the second loop in a long block }
define done3 = 33 { for exiting the third loop in a very long block }
define done4 = 34 { for exiting the fourth loop in an extremely long block }
define done5 = 35 { for exiting the fifth loop in an immense block }
define done6 = 36 { for exiting the sixth loop in a block }
define found = 40 { go here when you've found it }
define found1 = 41 { like found, when there's more than one per routine }
define found2 = 42 { like found, when there's more than two per routine }
define not_found = 45 { go here when you've found nothing }
define common_ending = 50 { go here when you want to merge with another branch }

```

**16.** Here are some macros for common programming idioms.

```

define negate(#) ≡ # ← -# { change the sign of a variable }
define loop ≡ while true do { repeat over and over until a goto happens }
format loop ≡ xclause { WEB's xclause acts like 'while true do' }
define do_nothing ≡ { empty statement }
define return ≡ goto exit { terminate a procedure call }
format return ≡ nil
define empty = 0 { symbolic name for a null constant }

```

**17. The character set.** In order to make T<sub>E</sub>X readily portable to a wide variety of computers, all of its input text is converted to an internal eight-bit code that includes standard ASCII, the “American Standard Code for Information Interchange.” This conversion is done immediately when each character is read in. Conversely, characters are converted from ASCII to the user’s external representation just before they are output to a text file.

Such an internal code is relevant to users of T<sub>E</sub>X primarily because it governs the positions of characters in the fonts. For example, the character ‘A’ has ASCII code 65 = ‘101’, and when T<sub>E</sub>X typesets this letter it specifies character number 65 in the current font. If that font actually has ‘A’ in a different position, T<sub>E</sub>X doesn’t know what the real position is; the program that does the actual printing from T<sub>E</sub>X’s device-independent files is responsible for converting from ASCII to a particular font encoding.

T<sub>E</sub>X’s internal code also defines the value of constants that begin with a reverse apostrophe; and it provides an index to the `\catcode`, `\mathcode`, `\uccode`, `\lccode`, and `\delcode` tables.

**18.** Characters of text that have been converted to T<sub>E</sub>X’s internal form are said to be of type *ASCII\_code*, which is a subrange of the integers.

```
⟨Types in the outer block 18⟩ ≡
  ASCII_code = 0 .. 255; { eight-bit numbers }
  KANJI_code = 0 .. 65535; { sixteen-bit numbers }
```

See also sections 25, 39, 102, 110, 114, 156, 218, 275, 306, 559, 605, 931, and 936.

This code is used in section 4.

**19.** The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for typesetting; so the present specification of T<sub>E</sub>X has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes ‘40 through ‘176; all of these characters are now available on most computer terminals.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name *char* for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider *char* to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name *text\_char* to stand for the data type of the characters that are converted to and from *ASCII\_code* when they are input and output. We shall also assume that *text\_char* consists of the elements *chr(first\_text\_char)* through *chr(last\_text\_char)*, inclusive. The following definitions should be adjusted if necessary.

```
define text_char ≡ ASCII_code { the data type of characters in text files }
define first_text_char = 0 { ordinal number of the smallest element of text_char }
define last_text_char = 255 { ordinal number of the largest element of text_char }
```

```
⟨Local variables for initialization 19⟩ ≡
```

```
i: integer;
```

See also sections 169 and 938.

This code is used in section 4.

**20.** The T<sub>E</sub>X processor converts between ASCII code and the user’s external character set by means of arrays *xord* and *xchr* that are analogous to Pascal’s *ord* and *chr* functions.

```
⟨Global variables 13⟩ +=
xord: array [text_char] of ASCII_code; { specifies conversion of input characters }
xchr: array [ASCII_code] of text_char; { specifies conversion of output characters }
xprn: array [ASCII_code] of ASCII_code; { non zero iff character is printable }
```

**21.** Since we are assuming that our Pascal system is able to read and write the visible characters of standard ASCII (although not necessarily using the ASCII codes to represent them), the following assignment statements initialize the standard part of the *xchr* array properly, without needing any system-dependent changes. On the other hand, it is possible to implement TEX with less complete character sets, and in such cases it will be necessary to change something here.

```

⟨Set initial values of key variables 21⟩ ≡
  xchr[40] ← '□'; xchr[41] ← '!'; xchr[42] ← '"'; xchr[43] ← '#'; xchr[44] ← '$';
  xchr[45] ← '%'; xchr[46] ← '&'; xchr[47] ← '^^';
  xchr[50] ← '('; xchr[51] ← ')'; xchr[52] ← '*'; xchr[53] ← '+'; xchr[54] ← ',';
  xchr[55] ← '-'; xchr[56] ← '.'; xchr[57] ← '/';
  xchr[60] ← '0'; xchr[61] ← '1'; xchr[62] ← '2'; xchr[63] ← '3'; xchr[64] ← '4';
  xchr[65] ← '5'; xchr[66] ← '6'; xchr[67] ← '7';
  xchr[70] ← '8'; xchr[71] ← '9'; xchr[72] ← ':'; xchr[73] ← ';'; xchr[74] ← '<';
  xchr[75] ← '='; xchr[76] ← '>'; xchr[77] ← '?';
  xchr[100] ← '@'; xchr[101] ← 'A'; xchr[102] ← 'B'; xchr[103] ← 'C'; xchr[104] ← 'D';
  xchr[105] ← 'E'; xchr[106] ← 'F'; xchr[107] ← 'G';

This code is used in section 8.

**22.** Some of the ASCII codes without visible characters have been given symbolic names in this program because they are used with a special meaning.

```

define null_code = '0' { ASCII code that might disappear }
define carriage_return = '15' { ASCII code used at end of line }
define invalid_code = '177' { ASCII code that many systems prohibit in text files }

```

**23.** The ASCII code is “standard” only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. Appendix C of *The T<sub>E</sub>Xbook* gives a complete specification of the intended correspondence between characters and T<sub>E</sub>X’s internal representation.

If T<sub>E</sub>X is being used on a garden-variety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn’t really matter what codes are specified in *xchr*[0 .. ‘37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of *xchr* will make T<sub>E</sub>X more friendly on computers that have an extended character set, so that users can type things like ‘#’ instead of ‘\ne’. People with extended character sets can assign codes arbitrarily, giving an *xchr* equivalent to whatever characters the users of T<sub>E</sub>X are allowed to have in their input files. It is best to make the codes correspond to the intended interpretations as shown in Appendix C whenever possible; but this is not necessary. For example, in countries with an alphabet of more than 26 letters, it is usually best to map the additional letters into codes less than ‘40. To get the most “permissive” character set, change ‘\_’ on the right of these assignment statements to *chr*(*i*).

```
⟨Set initial values of key variables 21⟩ +=
  { Initialize xchr to the identity mapping. }
  for i ← 0 to ‘37 do xchr[i] ← i;
  for i ← ‘177 to ‘377 do xchr[i] ← i;
```

**24.** The following system-independent code makes the *xord* array contain a suitable inverse to the information in *xchr*. Note that if *xchr*[*i*] = *xchr*[*j*] where *i* < *j* < ‘177, the value of *xord*[*xchr*[*i*]] will turn out to be *j* or more; hence, standard ASCII code numbers will be used instead of codes below ‘40 in case there is a coincidence.

```
⟨Set initial values of key variables 21⟩ +=
  for i ← first_text_char to last_text_char do xord[chr(i)] ← invalid_code;
  for i ← ‘200 to ‘377 do xord[xchr[i]] ← i;
  for i ← 0 to ‘176 do xord[xchr[i]] ← i; { Set xprn for printable ASCII, unless eight_bit_p is set. }
  for i ← 0 to 255 do xprn[i] ← (eight_bit_p ∨ ((i ≥ “_”) ∧ (i ≤ “~”))); { The idea for this dynamic
    translation comes from the patch by Libor Skarvada <libor@informatics.muni.cz> and Petr
    Sojka <sojka@informatics.muni.cz>. I didn’t use any of the actual code, though, preferring a
    more general approach. }
  { This updates the xchr, xord, and xprn arrays from the provided translate_filename. See the
    function definition in texmfmp.c for more comments. }
  if translate_filename then read_tcx_file;
```

**25. Input and output.** The bane of portability is the fact that different operating systems treat input and output quite differently, perhaps because computer scientists have not given sufficient attention to this problem. People have felt somehow that input and output are not part of “real” programming. Well, it is true that some kinds of programming are more fun than others. With existing input/output conventions being so diverse and so messy, the only sources of joy in such parts of the code are the rare occasions when one can find a way to make the program a little less bad than it might have been. We have two choices, either to attack I/O now and get it over with, or to postpone I/O until near the end. Neither prospect is very attractive, so let’s get it over with.

The basic operations we need to do are (1) inputting and outputting of text, to or from a file or the user’s terminal; (2) inputting and outputting of eight-bit bytes, to or from a file; (3) instructing the operating system to initiate (“open”) or to terminate (“close”) input or output from a specified file; (4) testing whether the end of an input file has been reached.

T<sub>E</sub>X needs to deal with two kinds of files. We shall use the term *alpha\_file* for a file that contains textual data, and the term *byte\_file* for a file that contains eight-bit binary information. These two types turn out to be the same on many computers, but sometimes there is a significant distinction, so we shall be careful to distinguish between them. Standard protocols for transferring such files from computer to computer, via high-speed networks, are now becoming available to more and more communities of users.

The program actually makes use also of a third kind of file, called a *word\_file*, when dumping and reloading base information for its own initialization. We shall define a word file later; but it will be possible for us to specify simple operations on word files before they are defined.

```

⟨Types in the outer block 18⟩ +=
  eight_bits = 0 .. 255; { unsigned one-byte quantity }
  sixteen_bits = 0 .. 65535; { unsigned two-bytes quantity }
  alpha_file = packed file of text_char; { files that contain textual data }
  byte_file = packed file of eight_bits; { files that contain binary data }

```

**26.** Most of what we need to do with respect to input and output can be handled by the I/O facilities that are standard in Pascal, i.e., the routines called *get*, *put*, *eof*, and so on. But standard Pascal does not allow file variables to be associated with file names that are determined at run time, so it cannot be used to implement T<sub>E</sub>X; some sort of extension to Pascal’s ordinary *reset* and *rewrite* is crucial for our purposes. We shall assume that *name\_of\_file* is a variable of an appropriate type such that the Pascal run-time system being used to implement T<sub>E</sub>X can open a file whose external name is specified by *name\_of\_file*.

```

⟨Global variables 13⟩ +=
name_of_file: ↑text_char;
name_length: 0 .. file_name_size;
  { this many characters are actually relevant in name_of_file (the rest are blank) }

```

**27.** All of the file opening functions are defined in C.

**28.** Kanji code handling.

**29.** And all the file closing routines as well.

**30.** Binary input and output are done with Pascal’s ordinary *get* and *put* procedures, so we don’t have to make any other special arrangements for binary I/O. Text output is also easy to do with standard Pascal routines. The treatment of text input is more difficult, however, because of the necessary translation to *ASCII\_code* values. T<sub>E</sub>X’s conventions should be efficient, and they should blend nicely with the user’s operating environment.

**31.** Input from text files is read one line at a time, using a routine called *input\_ln*. This function is defined in terms of global variables called *buffer*, *first*, and *last* that will be described in detail later; for now, it suffices for us to know that *buffer* is an array of *ASCII\_code* values, and that *first* and *last* are indices into this array representing the beginning and ending of a line of text.

```

⟨Global variables 13⟩ +=
buffer: ↑ASCII_code; { lines of characters being read }
first: 0 .. buf_size; { the first unused position in buffer }
last: 0 .. buf_size; { end of the line just input to buffer }
max_buf_stack: 0 .. buf_size; { largest index used in buffer }

```

**32.** The *input\_ln* function brings the next line of input from the specified file into available positions of the buffer array and returns the value *true*, unless the file has already been entirely read, in which case it returns *false* and sets *last* ← *first*. In general, the *ASCII\_code* numbers that represent the next line of the file are input into *buffer[first]*, *buffer[first + 1]*, ..., *buffer[last - 1]*; and the global variable *last* is set equal to *first* plus the length of the line. Trailing blanks are removed from the line; thus, either *last* = *first* (in which case the line was entirely blank) or *buffer[last - 1]* ≠ "␣".

An overflow error is given, however, if the normal actions of *input\_ln* would make *last* ≥ *buf\_size*; this is done so that other parts of T<sub>E</sub>X can safely look at the contents of *buffer[last + 1]* without overstepping the bounds of the *buffer* array. Upon entry to *input\_ln*, the condition *first* < *buf\_size* will always hold, so that there is always room for an “empty” line.

The variable *max\_buf\_stack*, which is used to keep track of how large the *buf\_size* parameter must be to accommodate the present job, is also kept up to date by *input\_ln*.

If the *bypass\_eoln* parameter is *true*, *input\_ln* will do a *get* before looking at the first character of the line; this skips over an *eoln* that was in *f*↑. The procedure does not do a *get* when it reaches the end of the line; therefore it can be used to acquire input from the user’s terminal as well as from ordinary text files.

Standard Pascal says that a file should have *eoln* immediately before *eof*, but T<sub>E</sub>X needs only a weaker restriction: If *eof* occurs in the middle of a line, the system function *eoln* should return a *true* result (even though *f*↑ will be undefined).

Since the inner loop of *input\_ln* is part of T<sub>E</sub>X’s “inner loop”—each character of input comes in at this place—it is wise to reduce system overhead by making use of special routines that read in an entire array of characters at once, if such routines are available. The following code uses standard Pascal to illustrate what needs to be done, but finer tuning is often possible at well-developed Pascal sites.

We define *input\_ln* in C, for efficiency. Nevertheless we quote the module ‘Report overflow of the input buffer, and abort’ here in order to make WEAVE happy, since part of that module is needed by e-TeX.

```
@{(Report overflow of the input buffer, and abort 36)}@}
```

**33.** The user's terminal acts essentially like other files of text, except that it is used both for input and for output. When the terminal is considered an input file, the file variable is called *term.in*, and when it is considered an output file the file variable is *term.out*.

```
define term.in ≡ stdin { the terminal as an input file }
define term.out ≡ stdout { the terminal as an output file }
```

⟨Global variables 13⟩ +≡

```
init ini_version: boolean; { are we INITEX? }

```

**34.** Here is how to open the terminal files. *t\_open\_out* does nothing. *t\_open\_in*, on the other hand, does the work of “rescanning,” or getting any command line arguments the user has provided. It’s defined in C.

```
define t_open_out ≡ { output already open for text output }
```

**35.** Sometimes it is necessary to synchronize the input/output mixture that happens on the user’s terminal, and three system-dependent procedures are used for this purpose. The first of these, *update\_terminal*, is called when we want to make sure that everything we have output to the terminal so far has actually left the computer’s internal buffers and been sent. The second, *clear\_terminal*, is called when we wish to cancel any input that the user may have typed ahead (since we are about to issue an unexpected error message). The third, *wake\_up\_terminal*, is supposed to revive the terminal if the user has disabled it by some instruction to the operating system. The following macros show how these operations can be specified with UNIX. *update\_terminal* does an *fflush*. *clear\_terminal* is redefined to do nothing, since the user should control the terminal.

```
define update_terminal ≡ fflush(term_out)
```

```
define clear_terminal ≡ do_nothing
```

```
define wake_up_terminal ≡ do_nothing { cancel the user’s cancellation of output }
```

**36.** We need a special routine to read the first line of TEX input from the user's terminal. This line is different because it is read before we have opened the transcript file; there is sort of a "chicken and egg" problem here. If the user types `\input paper` on the first line, or if some macro invoked by that line does such an `\input`, the transcript file will be named `paper.log`; but if no `\input` commands are performed during the first line of terminal input, the transcript file will acquire its default name `texput.log`. (The transcript file will not contain error messages generated by the first line before the first `\input` command.)

The first line is even more special if we are lucky enough to have an operating system that treats TEX differently from a run-of-the-mill Pascal object program. It's nice to let the user start running a TEX job by typing a command line like `tex paper`; in such a case, TEX will operate as if the first line of input were `paper`, i.e., the first line will consist of the remainder of the command line, after the part that invoked TEX.

The first line is special also because it may be read before TEX has input a format file. In such cases, normal error messages cannot yet be given. The following code uses concepts that will be explained later. (If the Pascal compiler does not support non-local `goto`, the statement `goto final_end` should be replaced by something that quietly terminates the program.)

Routine is implemented in C; part of module is, however, needed for e-TeX.

`<Report overflow of the input buffer, and abort 36> ≡`

```
begin cur_input.loc_field ← first; cur_input.limit_field ← last - 1; overflow("buffer_size", buf_size);
end
```

This code is used in section 32.

**37.** Different systems have different ways to get started. But regardless of what conventions are adopted, the routine that initializes the terminal should satisfy the following specifications:

- 1) It should open file `term.in` for input from the terminal. (The file `term.out` will already be open for output to the terminal.)
- 2) If the user has given a command line, this line should be considered the first line of terminal input. Otherwise the user should be prompted with `**`, and the first line of input should be whatever is typed in response.
- 3) The first line of input, which might or might not be a command line, should appear in locations `first` to `last - 1` of the `buffer` array.
- 4) The global variable `loc` should be set so that the character to be read next by TEX is in `buffer[loc]`. This character should not be blank, and we should have `loc < last`.

(It may be necessary to prompt the user several times before a non-blank line comes in. The prompt is `**` instead of the later `*` because the meaning is slightly different: `\input` need not be typed immediately after `**`.)

```
define loc ≡ cur_input.loc_field { location of first unread character in buffer }
```

**38.** The following program does the required initialization. Iff anything has been specified on the command line, then *t\_open\_in* will return with *last* > *first*.

```

function init_terminal: boolean; { gets the terminal input started }
  label exit;
  begin t_open_in;
  if last > first then
    begin loc ← first;
    while (loc < last) ∧ (buffer[loc] = ' ') do incr(loc);
    if loc < last then
      begin init_terminal ← true; goto exit;
      end;
    end;
  loop begin wake_up_terminal; write(term_out, '**'); update_terminal;
  if ¬input_ln(term_in, true) then { this shouldn't happen }
    begin write_ln(term_out); write_ln(term_out, '! End of file on the terminal... why?');
    init_terminal ← false; return;
    end;
  loc ← first;
  while (loc < last) ∧ (buffer[loc] = " ") do incr(loc);
  if loc < last then
    begin init_terminal ← true; return; { return unless the line was all blank }
    end;
  write_ln(term_out, 'Please type the name of your input file. ');
  end;
exit: end;

```

**39. String handling.** Control sequence names and diagnostic messages are variable-length strings of eight-bit characters. Since Pascal does not have a well-developed string mechanism, T<sub>E</sub>X does all of its string processing by homegrown methods.

Elaborate facilities for dynamic strings are not needed, so all of the necessary operations can be handled with a simple data structure. The array *str\_pool* contains all of the (eight-bit) ASCII codes in all of the strings, and the array *str\_start* contains indices of the starting points of each string. Strings are referred to by integer numbers, so that string number *s* comprises the characters *str\_pool*[*j*] for *str\_start*[*s*] ≤ *j* < *str\_start*[*s* + 1]. Additional integer variables *pool\_ptr* and *str\_ptr* indicate the number of entries used so far in *str\_pool* and *str\_start*, respectively; locations *str\_pool*[*pool\_ptr*] and *str\_start*[*str\_ptr*] are ready for the next string to be allocated.

String numbers 0 to 255 are reserved for strings that correspond to single ASCII characters. This is in accordance with the conventions of WEB, which converts single-character strings into the ASCII code number of the single character involved, while it converts other strings into integers and builds a string pool file. Thus, when the string constant "." appears in the program below, WEB converts it into the integer 46, which is the ASCII code for a period, while WEB will convert a string like "hello" into some integer greater than 255. String number 46 will presumably be the single character '.'; but some ASCII codes have no standard visible representation, and T<sub>E</sub>X sometimes needs to be able to print an arbitrary ASCII character, so the first 256 strings are used to specify exactly what should be printed for each of the 256 possibilities.

Elements of the *str\_pool* array must be ASCII codes that can actually be printed; i.e., they must have an *xchr* equivalent in the local character set. (This restriction applies only to preloaded strings, not to those generated dynamically by the user.)

Some Pascal compilers won't pack integers into a single byte unless the integers lie in the range -128 .. 127. To accommodate such systems we access the string pool only via macros that can easily be redefined.

```
define si(#) ≡ # { convert from ASCII_code to packed_ASCII_code }
```

```
define so(#) ≡ # { convert from packed_ASCII_code to ASCII_code }
```

⟨Types in the outer block 18⟩ +≡

```
pool_pointer = integer; { for variables that point into str_pool }
```

```
str_number = 0 .. ssup_max_strings; { for variables that point into str_start }
```

```
packed_ASCII_code = 0 .. 255; { elements of str_pool array }
```

**40.** ⟨Global variables 13⟩ +≡

```
str_pool: ↑packed_ASCII_code; { the characters }
```

```
str_start: ↑pool_pointer; { the starting pointers }
```

```
pool_ptr: pool_pointer; { first unused position in str_pool }
```

```
str_ptr: str_number; { number of the current string being created }
```

```
init_pool_ptr: pool_pointer; { the starting value of pool_ptr }
```

```
init_str_ptr: str_number; { the starting value of str_ptr }
```

**41.** Several of the elementary string operations are performed using WEB macros instead of Pascal procedures, because many of the operations are done quite frequently and we want to avoid the overhead of procedure calls. For example, here is a simple macro that computes the length of a string.

```
define length(#) ≡ (str_start[# + 1] - str_start[#]) { the number of characters in string number # }
```

**42.** The length of the current string is called *cur\_length*:

```
define cur_length ≡ (pool_ptr - str_start[str_ptr])
```

**43.** Strings are created by appending character codes to *str\_pool*. The *append\_char* macro, defined here, does not check to see if the value of *pool\_ptr* has gotten too high; this test is supposed to be made before *append\_char* is used. There is also a *flush\_char* macro, which erases the last character appended.

To test if there is room to append *l* more characters to *str\_pool*, we shall write *str\_room(l)*, which aborts T<sub>E</sub>X and gives an apologetic error message if there isn't enough room.

```

define append_char(#) ≡ { put ASCII_code # at the end of str_pool }
      begin str_pool[pool_ptr] ← si(#); incr(pool_ptr);
      end
define flush_char ≡ decr(pool_ptr) { forget the last character in the pool }
define str_room(#) ≡ { make sure that the pool hasn't overflowed }
      begin if pool_ptr + # > pool_size then overflow("pool_size", pool_size - init_pool_ptr);
      end

```

**44.** Once a sequence of characters has been appended to *str\_pool*, it officially becomes a string when the function *make\_string* is called. This function returns the identification number of the new string as its value.

```

function make_string: str_number; { current string enters the pool }
      begin if str_ptr = max_strings then overflow("number_of_strings", max_strings - init_str_ptr);
      incr(str_ptr); str_start[str_ptr] ← pool_ptr; make_string ← str_ptr - 1;
      end;

```

**45.** To destroy the most recently made string, we say *flush\_string*.

```

define flush_string ≡
      begin decr(str_ptr); pool_ptr ← str_start[str_ptr];
      end

```

**46.** The following subroutine compares string *s* with another string of the same length that appears in *buffer* starting at position *k*; the result is *true* if and only if the strings are equal. Empirical tests indicate that *str\_eq\_buf* is used in such a way that it tends to return *true* about 80 percent of the time.

```

function str_eq_buf(s : str_number; k : integer): boolean; { test equality of strings }
      label not_found; { loop exit }
      var j: pool_pointer; { running index }
      result: boolean; { result of comparison }
      begin j ← str_start[s];
      while j < str_start[s + 1] do
        begin if so(str_pool[j]) ≠ buffer[k] then
          begin result ← false; goto not_found;
          end;
        incr(j); incr(k);
        end;
      result ← true;
      not_found: str_eq_buf ← result;
      end;

```

47. Here is a similar routine, but it compares two strings in the string pool, and it does not assume that they have the same length.

```

function str_eq_str(s, t : str_number): boolean; { test equality of strings }
  label not_found; { loop exit }
  var j, k: pool_pointer; { running indices }
      result: boolean; { result of comparison }
  begin result ← false;
  if length(s) ≠ length(t) then goto not_found;
  j ← str_start[s]; k ← str_start[t];
  while j < str_start[s + 1] do
    begin if str_pool[j] ≠ str_pool[k] then goto not_found;
    incr(j); incr(k);
    end;
  result ← true;
not_found: str_eq_str ← result;
end;

```

48. The initial values of *str\_pool*, *str\_start*, *pool\_ptr*, and *str\_ptr* are computed by the INITEX program, based in part on the information that WEB has output while processing TEX.

⟨Declare additional routines for string recycling 1402⟩

```

init function get_strings_started: boolean;
    { initializes the string pool, but returns false if something goes wrong }
label done, exit;
var k, l: KANJI_code; { small indices or counters }
    m, n: text_char; { characters input from pool_file }
    g: str_number; { garbage }
    a: integer; { accumulator for check sum }
    c: boolean; { check sum has been checked }
begin pool_ptr ← 0; str_ptr ← 0; str_start[0] ← 0; ⟨Make the first 256 strings 49⟩;
    ⟨Read the other strings from the TEX.POOL file and return true, or give an error message and return
      false 52⟩;
exit: end;
tini

```

```

49. define app_lc_hex(#) ≡ l ← #;
    if l < 10 then append_char(l + "0") else append_char(l - 10 + "a")

```

⟨Make the first 256 strings 49⟩ ≡

```

for k ← 0 to 255 do
  begin if (⟨Character k cannot be printed 50⟩) then
    begin append_char("^"); append_char("^");
    if k < '100 then append_char(k + '100)
    else if k < '200 then append_char(k - '100)
      else begin app_lc_hex(k div 16); app_lc_hex(k mod 16);
      end;
    end
  else append_char(k);
  g ← make_string;
end

```

This code is used in section 48.

**50.** The first 128 strings will contain 95 standard ASCII characters, and the other 33 characters will be printed in three-symbol form like ‘ $\^{\wedge}$ A’ unless a system-dependent change is made here. Installations that have an extended character set, where for example  $xchr[‘32] = ‘\#‘$ , would like string ‘32 to be printed as the single character ‘32 instead of the three characters ‘136, ‘136, ‘132 ( $\^{\wedge}$ Z). On the other hand, even people with an extended character set will want to represent string ‘15 by  $\^{\wedge}$ M, since ‘15 is *carriage\_return*; the idea is to produce visible strings instead of tabs or line-feeds or carriage-returns or bell-rings or characters that are treated anomalously in text files.

Unprintable characters of codes 128–255 are, similarly, rendered  $\^{\wedge}$ 80– $\^{\wedge}$ ff.

The boolean expression defined here should be *true* unless T<sub>E</sub>X internal code number  $k$  corresponds to a non-troublesome visible symbol in the local character set. An appropriate formula for the extended character set recommended in *The T<sub>E</sub>Xbook* would, for example, be ‘ $k \in [0, ‘10 .. ‘12, ‘14, ‘15, ‘33, ‘177 .. ‘377]$ ’. If character  $k$  cannot be printed, and  $k < ‘200$ , then character  $k + ‘100$  or  $k - ‘100$  must be printable; moreover, ASCII codes [‘41 .. ‘46, ‘60 .. ‘71, ‘136, ‘141 .. ‘146, ‘160 .. ‘171] must be printable. Thus, at least 81 printable characters are needed.

```
< Character  $k$  cannot be printed 50 > ≡
  ¬(ismultiprn( $k$ ) ∨ xprn[ $k$ ])
```

This code is used in section 49.

**51.** When the WEB system program called TANGLE processes the TEX.WEB description that you are now reading, it outputs the Pascal program TEX.PAS and also a string pool file called TEX.POOL. The INITEX program reads the latter file, where each string appears as a two-digit decimal length followed by the string itself, and the information is recorded in T<sub>E</sub>X’s string memory.

```
< Global variables 13 > +≡
  init pool_file: alpha_file; { the string-pool file output by TANGLE }
  tini
```

```
52. define bad_pool(#) ≡
  begin wake_up_terminal; write_ln(term_out, #); a_close(pool_file); get_strings_started ← false;
  return;
  end
```

```
< Read the other strings from the TEX.POOL file and return true, or give an error message and return
  false 52 > ≡
  name_length ← strlen(pool_name); name_of_file ← xmalloc_array(ASCII_code, name_length + 1);
  strcpy(stringcast(name_of_file + 1), pool_name); { copy the string }
  if a_open_in(pool_file, kpse_texpool_format) then
    begin c ← false;
    repeat < Read one string, but return false if the string memory space is getting too tight for
      comfort 53 >;
    until c;
    a_close(pool_file); get_strings_started ← true;
  end
  else bad_pool(‘!_I_can’t_read_’, pool_name, ‘;_bad_path?’)
```

This code is used in section 48.

**53.**  $\langle$  Read one string, but return *false* if the string memory space is getting too tight for comfort 53  $\rangle \equiv$

```

begin if eof(pool_file) then bad_pool('!_', pool_name, '~has_no_check_sum.~');
read(pool_file, m); read(pool_file, n); { read two digits of string length }
if m = '~*' then  $\langle$  Check the pool check sum 54  $\rangle$ 
else begin if (xord[m] < "0")  $\vee$  (xord[m] > "9")  $\vee$  (xord[n] < "0")  $\vee$  (xord[n] > "9") then
  bad_pool('!_', pool_name, '~line_doesn~t_begin_with_two_digits.~');
  l  $\leftarrow$  xord[m] * 10 + xord[n] - "0" * 11; { compute the length }
  if pool_ptr + l + string_vacancies > pool_size then bad_pool('!_You_have_to_increase_POOLSIZE.~');
  for k  $\leftarrow$  1 to l do
    begin if eoln(pool_file) then m  $\leftarrow$  '~_' else read(pool_file, m);
    append_char(xord[m]);
    end;
  read_ln(pool_file); g  $\leftarrow$  make_string;
  end;
end

```

This code is used in section 52.

**54.** The WEB operation @ $\$$  denotes the value that should be at the end of this TEX.POOL file; any other value means that the wrong pool file has been loaded.

$\langle$  Check the pool check sum 54  $\rangle \equiv$

```

begin a  $\leftarrow$  0; k  $\leftarrow$  1;
loop begin if (xord[n] < "0")  $\vee$  (xord[n] > "9") then
  bad_pool('!_', pool_name, '~check_sum_doesn~t_have_nine_digits.~');
  a  $\leftarrow$  10 * a + xord[n] - "0";
  if k = 9 then goto done;
  incr(k); read(pool_file, n);
  end;
done: if a  $\neq$  @$ then
  bad_pool('!_', pool_name, '~doesn~t_match;_tangle_me_again_(or_fix_the_path).~');
  c  $\leftarrow$  true;
end

```

This code is used in section 53.

**55. On-line and off-line printing.** Messages that are sent to a user's terminal and to the transcript-log file are produced by several '*print*' procedures. These procedures will direct their output to a variety of places, based on the setting of the global variable *selector*, which has the following possible values:

*term\_and\_log*, the normal setting, prints on the terminal and on the transcript file.

*log\_only*, prints only on the transcript file.

*term\_only*, prints only on the terminal.

*no\_print*, doesn't print at all. This is used only in rare cases before the transcript file is open.

*pseudo*, puts output into a cyclic buffer that is used by the *show\_context* routine; when we get to that routine we shall discuss the reasoning behind this curious mode.

*new\_string*, appends the output to the current string in the string pool.

0 to 15, prints on one of the sixteen files for `\write` output.

The symbolic names '*term\_and\_log*', etc., have been assigned numeric codes that satisfy the convenient relations  $no\_print + 1 = term\_only$ ,  $no\_print + 2 = log\_only$ ,  $term\_only + 2 = log\_only + 1 = term\_and\_log$ .

Three additional global variables, *tally* and *term\_offset* and *file\_offset*, record the number of characters that have been printed since they were most recently cleared to zero. We use *tally* to record the length of (possibly very long) stretches of printing; *term\_offset* and *file\_offset*, on the other hand, keep track of how many characters have appeared so far on the current line that has been output to the terminal or to the transcript file, respectively.

```

define no_print = 16 { selector setting that makes data disappear }
define term_only = 17 { printing is destined for the terminal only }
define log_only = 18 { printing is destined for the transcript file only }
define term_and_log = 19 { normal selector setting }
define pseudo = 20 { special selector setting for show_context }
define new_string = 21 { printing is deflected to the string pool }
define max_selector = 21 { highest selector setting }

```

⟨Global variables 13⟩ +≡

*log\_file*: *alpha\_file*; { transcript of T<sub>E</sub>X session }

*selector*: 0 .. *max\_selector*; { where to print a message }

*dig*: **array** [0 .. 22] **of** 0 .. 15; { digits in a number being output }

*tally*: *integer*; { the number of characters recently printed }

*term\_offset*: 0 .. *max\_print\_line*; { the number of characters on the current terminal line }

*file\_offset*: 0 .. *max\_print\_line*; { the number of characters on the current file line }

*trick\_buf*: **array** [0 .. *ssup\_error\_line*] **of** *ASCII\_code*; { circular buffer for pseudoprinting }

*trick\_buf2*: **array** [0 .. *ssup\_error\_line*] **of** 0 .. 2; { pTeX: buffer for KANJI }

*kcode\_pos*: 0 .. 2; { pTeX: denotes whether first byte or second byte of KANJI }

*prev\_char*: *ASCII\_code*;

*trick\_count*: *integer*; { threshold for pseudoprinting, explained later }

*first\_count*: *integer*; { another variable for pseudoprinting }

**56.** ⟨Initialize the output routines 56⟩ ≡

```

selector ← term_only; tally ← 0; term_offset ← 0; file_offset ← 0; kcode_pos ← 0;

```

See also sections 62, 539, and 544.

This code is used in section 1345.

**57.** Macro abbreviations for output to the terminal and to the log file are defined here for convenience. Some systems need special conventions for terminal output, and it is possible to adhere to those conventions by changing *wterm*, *wterm.ln*, and *wterm.cr* in this section.

```

define wterm(#) ≡ write(term_out, #)
define wterm.ln(#) ≡ write.ln(term_out, #)
define wterm.cr ≡ write.ln(term_out)
define wlog(#) ≡ write(log_file, #)
define wlog.ln(#) ≡ write.ln(log_file, #)
define wlog.cr ≡ write.ln(log_file)

```

**58.** To end a line of text output, we call *print.ln*.

⟨ Basic printing procedures 58 ⟩ ≡

```

procedure print.ln; { prints an end-of-line }
begin case selector of
  term_and_log: begin if kcode_pos = 1 then
    begin wterm(`␣`); wlog(`␣`);
    end;
    wterm.cr; wlog.cr; term_offset ← 0; file_offset ← 0;
    end;
  log_only: begin if kcode_pos = 1 then wlog(`␣`);
    wlog.cr; file_offset ← 0;
    end;
  term_only: begin if kcode_pos = 1 then wterm(`␣`);
    wterm.cr; term_offset ← 0;
    end;
  no_print, pseudo, new_string: do_nothing;
othercases write.ln(write_file[selector])
endcases;
kcode_pos ← 0;
end; { tally is not affected }

```

See also sections 59, 60, 61, 63, 64, 65, 66, 268, 269, 529, 710, 1368, 1395, 1398, 1467, and 1473.

This code is used in section 4.

59. The *print\_char* procedure sends one character to the desired destination, using the *xchr* array to map it into an external character compatible with *input\_ln*. All printing comes through *print\_ln* or *print\_char*.

⟨Basic printing procedures 58⟩ +=

```

procedure print_char(s : ASCII_code); { prints a single character }
  label exit; { label is not used but nonetheless kept (for other changes?) }
  begin if ⟨Character s is the current new-line character 250⟩ then
    if selector < pseudo then
      begin print_ln; return;
    end;
  if kcode_pos = 1 then kcode_pos ← 2
  else if iskanji1(xchr[s]) then
    begin kcode_pos ← 1;
    if (selector = term_and_log) ∨ (selector = log_only) then
      if file_offset ≥ max_print_line - 1 then
        begin wlog_cr; file_offset ← 0;
      end;
      if (selector = term_and_log) ∨ (selector = term_only) then
        if term_offset ≥ max_print_line - 1 then
          begin wterm_cr; term_offset ← 0;
        end;
      end
    else kcode_pos ← 0;
  case selector of
    term_and_log: begin wterm(xchr[s]); incr(term_offset);
      if term_offset = max_print_line then
        begin wterm_cr; term_offset ← 0;
      end;
      wlog(xchr[s]); incr(file_offset);
      if file_offset = max_print_line then
        begin wlog_cr; file_offset ← 0;
      end;
    end;
    log_only: begin wlog(xchr[s]); incr(file_offset);
      if file_offset = max_print_line then print_ln;
    end;
    term_only: begin wterm(xchr[s]); incr(term_offset);
      if term_offset = max_print_line then print_ln;
    end;
    no_print: do_nothing;
    pseudo: if tally < trick_count then
      begin trick_buf[tally mod error_line] ← s; trick_buf2[tally mod error_line] ← kcode_pos;
    end;
    new_string: begin if pool_ptr < pool_size then append_char(s);
      end; { we drop characters if the string space is full }
  othercases write(write_file[selector], xchr[s])
  endcases;
  incr(tally);
exit: end;

```

**60.** An entire string is output by calling *print*. Note that if we are outputting the single standard ASCII character *c*, we could call *print("c")*, since "c" = 99 is the number of a single-character string, as explained above. But *print\_char("c")* is quicker, so TEX goes directly to the *print\_char* routine when it knows that this is safe. (The present implementation assumes that it is always safe to print a visible ASCII character.)

⟨Basic printing procedures 58⟩ +≡

```

procedure print(s : integer); { prints string s }
  label exit;
  var j: pool_pointer; { current character code position }
      nl: integer; { new-line character to restore }
  begin if s ≥ str_ptr then s ← "???" { this can't happen }
  else if s < 256 then
    if s < 0 then s ← "???" { can't happen }
    else begin if selector > pseudo then
      begin print_char(s); return; { internal strings are not expanded }
    end;
    if ((Character s is the current new-line character 250)) then
      if selector < pseudo then
        begin print_ln; return;
      end;
      nl ← new_line_char; new_line_char ← -1; { temporarily disable new-line character }
      j ← str_start[s];
      while j < str_start[s + 1] do
        begin print_char(so(str_pool[j])); incr(j);
        end;
      new_line_char ← nl; return;
    end;
  j ← str_start[s];
  while j < str_start[s + 1] do
    begin print_char(so(str_pool[j])); incr(j);
    end;
  exit: end;

```

**61.** Control sequence names, file names, and strings constructed with `\string` might contain *ASCII\_code* values that can't be printed using *print\_char*. Therefore we use *slow\_print* for them:

⟨Basic printing procedures 58⟩ +≡

```

procedure slow_print(s : integer); { prints string s }
  var j: pool_pointer; { current character code position }
  begin if (s ≥ str_ptr) ∨ (s < 256) then print(s)
  else begin j ← str_start[s];
    while j < str_start[s + 1] do
      begin print(so(str_pool[j])); incr(j);
      end;
    end;
  end;
end;

```

62. Here is the very first thing that T<sub>E</sub>X prints: a headline that identifies the version number and format package. The *term\_offset* variable is temporarily incorrect, but the discrepancy is not serious since we assume that the banner and format identifier together will occupy at most *max\_print\_line* character positions.

```

⟨Initialize the output routines 56⟩ +≡
  if src_specials_p ∨ file_line_error_style_p ∨ parse_first_line_p then wterm(banner_k)
  else wterm(banner);
  wterm(␣); wterm(conststringcast(get_enc_string)); wterm(␣); wterm(version_string);
  if format_ident > 0 then slow_print(format_ident);
  print_ln;
  if shellenabled_p then
    begin wterm(␣);
    if restrictedshell then
      begin wterm(␣restricted␣);
      end;
    wterm_ln(␣\write18␣enabled.␣);
    end;
  if src_specials_p then
    begin wterm_ln(␣Source␣specials␣enabled.␣);
    end;
  if translate_filename then
    begin wterm(␣); fputs(translate_filename, stdout); wterm_ln(␣);
    end;
  update_terminal;

```

63. The procedure *print\_nl* is like *print*, but it makes sure that the string appears at the beginning of a new line.

```

⟨Basic printing procedures 58⟩ +≡
procedure print_nl(s : str_number); { prints string s at beginning of line }
  begin if ((term_offset > 0) ∧ (odd(selector))) ∨ ((file_offset > 0) ∧ (selector ≥ log_only)) then print_ln;
  print(s);
  end;

```

64. The procedure *print\_esc* prints a string that is preceded by the user's escape character (which is usually a backslash).

```

⟨Basic printing procedures 58⟩ +≡
procedure print_esc(s : str_number); { prints escape character, then s }
  var c : integer; { the escape character code }
  begin ⟨Set variable c to the current escape character 249⟩;
  if c ≥ 0 then
    if c < 256 then print(c);
  slow_print(s);
  end;

```

65. An array of digits in the range 0 .. 15 is printed by *print\_the\_digs*.

⟨Basic printing procedures 58⟩ +≡

```

procedure print_the_digs(k : eight_bits); { prints dig[k - 1] ... dig[0] }
  begin while k > 0 do
    begin decr(k);
    if dig[k] < 10 then print_char("0" + dig[k])
    else print_char("A" - 10 + dig[k]);
    end;
  end;

```

66. The following procedure, which prints out the decimal representation of a given integer *n*, has been written carefully so that it works properly if *n* = 0 or if (*-n*) would cause overflow. It does not apply **mod** or **div** to negative arguments, since such operations are not implemented consistently by all Pascal compilers.

⟨Basic printing procedures 58⟩ +≡

```

procedure print_int(n : integer); { prints an integer in decimal form }
  var k: 0 .. 23; { index to current digit; we assume that n < 1023 }
  m: integer; { used to negate n in possibly dangerous cases }
  begin k ← 0;
  if n < 0 then
    begin print_char("-");
    if n > -100000000 then negate(n)
    else begin m ← -1 - n; n ← m div 10; m ← (m mod 10) + 1; k ← 1;
      if m < 10 then dig[0] ← m
      else begin dig[0] ← 0; incr(n);
        end;
      end;
    end;
  repeat dig[k] ← n mod 10; n ← n div 10; incr(k);
  until n = 0;
  print_the_digs(k);
  end;

```

67. Here is a trivial procedure to print two digits; it is usually called with a parameter in the range  $0 \leq n \leq 99$ .

```

procedure print_two(n : integer); { prints two least significant digits }
  begin n ← abs(n) mod 100; print_char("0" + (n div 10)); print_char("0" + (n mod 10));
  end;

```

68. Hexadecimal printing of nonnegative integers is accomplished by *print\_hex*.

```

procedure print_hex(n : integer); { prints a positive integer in hexadecimal form }
  var k: 0 .. 22; { index to current digit; we assume that  $0 \leq n < 16^{22}$  }
  begin k ← 0; print_char("");
  repeat dig[k] ← n mod 16; n ← n div 16; incr(k);
  until n = 0;
  print_the_digs(k);
  end;

```

69. Old versions of TEX needed a procedure called *print\_ASCII* whose function is now subsumed by *print*. We retain the old name here as a possible aid to future software archæologists.

```

define print_ASCII ≡ print

```

70. Roman numerals are produced by the *print\_roman\_int* routine. Readers who like puzzles might enjoy trying to figure out how this tricky code works; therefore no explanation will be given. Notice that 1990 yields *mcmxc*, not *mxm*.

```

procedure print_roman_int(n : integer);
  label exit;
  var j, k: pool_pointer; { mysterious indices into str_pool }
      u, v: nonnegative_integer; { mysterious numbers }
  begin j ← str_start["m2d5c215x2v5i"]; v ← 1000;
  loop begin while n ≥ v do
    begin print_char(so(str_pool[j])); n ← n - v;
    end;
    if n ≤ 0 then return; { nonpositive input produces no output }
    k ← j + 2; u ← v div (so(str_pool[k - 1]) - "0");
    if str_pool[k - 1] = si("2") then
      begin k ← k + 2; u ← u div (so(str_pool[k - 1]) - "0");
      end;
    if n + u ≥ v then
      begin print_char(so(str_pool[k])); n ← n + u;
      end
    else begin j ← j + 2; v ← v div (so(str_pool[j - 1]) - "0");
    end;
  end;
exit: end;

```

71. The *print* subroutine will not print a string that is still being created. The following procedure will.

```

procedure print_current_string; { prints a yet-unmade string }
  var j: pool_pointer; { points to current character code }
  begin j ← str_start[str_ptr];
  while j < pool_ptr do
    begin print_char(so(str_pool[j])); incr(j);
    end;
  end;

```

72. Here is a procedure that asks the user to type a line of input, assuming that the *selector* setting is either *term\_only* or *term\_and\_log*. The input is placed into locations *first* through *last* - 1 of the *buffer* array, and echoed on the transcript file if appropriate.

This procedure is never called when *interaction* < *scroll\_mode*.

```

define prompt_input(#) ≡
  begin wake_up_terminal; print(#); term_input;
  end { prints a string and gets a line of input }
procedure term_input; { gets a line from the terminal }
  var k: 0 .. buf_size; { index into buffer }
  begin update_terminal; { now the user sees the prompt for sure }
  if ¬input_ln(term_in, true) then fatal_error("End_of_file_on_the_terminal!");
  term_offset ← 0; { the user's line ended with ⟨return⟩ }
  decr(selector); { prepare to echo the input }
  if last ≠ first then
    for k ← first to last - 1 do print(buffer[k]);
  print_ln; incr(selector); { restore previous status }
  end;

```

**73. Reporting errors.** When something anomalous is detected, TEX typically does something like this:

```
print_err("Something_anomalous_has_been_detected");
help3("This_is_the_first_line_of_my_offer_to_help.")
("This_is_the_second_line.I'm_trying_to")
("explain_the_best_way_for_you_to_proceed.");
error;
```

A two-line help message would be given using *help2*, etc.; these informal helps should use simple vocabulary that complements the words used in the official error message that was printed. (Outside the U.S.A., the help messages should preferably be translated into the local vernacular. Each line of help is at most 60 characters long, in the present implementation, so that *max\_print\_line* will not be exceeded.)

The *print\_err* procedure supplies a ‘!’ before the official message, and makes sure that the terminal is awake if a stop is going to occur. The *error* procedure supplies a ‘.’ after the official message, then it shows the location of the error; and if *interaction = error\_stop\_mode*, it also enters into a dialog with the user, during which time the help message may be printed.

**74.** The global variable *interaction* has four settings, representing increasing amounts of user interaction:

```
define batch_mode = 0 { omits all stops and omits terminal output }
define nonstop_mode = 1 { omits all stops }
define scroll_mode = 2 { omits error stops }
define error_stop_mode = 3 { stops at every opportunity to interact }
define unspecified_mode = 4 { extra value for command-line switch }
define print_err(#) ≡
  begin if interaction = error_stop_mode then wake_up_terminal;
  if file_line_error_style_p then print_file_line
  else print_nl("!");
  print(#);
  end
```

⟨Global variables 13⟩ +≡

*interaction*: *batch\_mode* .. *error\_stop\_mode*; { current level of interaction }

*interaction\_option*: *batch\_mode* .. *unspecified\_mode*; { set from command line }

**75.** ⟨Set initial values of key variables 21⟩ +≡

```
if interaction_option = unspecified_mode then interaction ← error_stop_mode
else interaction ← interaction_option;
```

**76.** TEX is careful not to call *error* when the print *selector* setting might be unusual. The only possible values of *selector* at the time of error messages are

*no\_print* (when *interaction = batch\_mode* and *log\_file* not yet open);

*term\_only* (when *interaction > batch\_mode* and *log\_file* not yet open);

*log\_only* (when *interaction = batch\_mode* and *log\_file* is open);

*term\_and\_log* (when *interaction > batch\_mode* and *log\_file* is open).

⟨Initialize the print *selector* based on *interaction* 76⟩ ≡

```
if interaction = batch_mode then selector ← no_print else selector ← term_only
```

This code is used in sections 1278 and 1350.

**77.** A global variable *deletions\_allowed* is set *false* if the *get\_next* routine is active when *error* is called; this ensures that *get\_next* and related routines like *get\_token* will never be called recursively. A similar interlock is provided by *set\_box\_allowed*.

The global variable *history* records the worst level of error that has been detected. It has four possible values: *spotless*, *warning\_issued*, *error\_message\_issued*, and *fatal\_error\_stop*.

Another global variable, *error\_count*, is increased by one when an *error* occurs without an interactive dialog, and it is reset to zero at the end of every paragraph. If *error\_count* reaches 100, T<sub>E</sub>X decides that there is no point in continuing further.

```

define spotless = 0 { history value when nothing has been amiss yet }
define warning_issued = 1 { history value when begin_diagnostic has been called }
define error_message_issued = 2 { history value when error has been called }
define fatal_error_stop = 3 { history value when termination was premature }

```

⟨Global variables 13⟩ +≡

*deletions\_allowed*: *boolean*; { is it safe for *error* to call *get\_token*? }

*set\_box\_allowed*: *boolean*; { is it safe to do a `\setbox` assignment? }

*history*: *spotless* .. *fatal\_error\_stop*; { has the source input been clean so far? }

*error\_count*: -1 .. 100; { the number of scrolled errors since the last paragraph ended }

**78.** The value of *history* is initially *fatal\_error\_stop*, but it will be changed to *spotless* if T<sub>E</sub>X survives the initialization process.

⟨Set initial values of key variables 21⟩ +≡

```

deletions_allowed ← true; set_box_allowed ← true; error_count ← 0; { history is initialized elsewhere }

```

**79.** Since errors can be detected almost anywhere in T<sub>E</sub>X, we want to declare the error procedures near the beginning of the program. But the error procedures in turn use some other procedures, which need to be declared *forward* before we get to *error* itself.

It is possible for *error* to be called recursively if some error arises when *get\_token* is being used to delete a token, and/or if some fatal error occurs while T<sub>E</sub>X is trying to fix a non-fatal one. But such recursion is never more than two levels deep.

⟨Error handling procedures 79⟩ ≡

```

procedure normalize_selector; forward;
procedure get_token; forward;
procedure term_input; forward;
procedure show_context; forward;
procedure begin_file_reading; forward;
procedure open_log_file; forward;
procedure close_files_and_terminate; forward;
procedure clear_for_error_prompt; forward;
procedure give_err_help; forward;
debug procedure debug_help; forward; gubed

```

See also sections 82, 83, 94, 95, and 96.

This code is used in section 4.

80. Individual lines of help are recorded in the array *help\_line*, which contains entries in positions 0 .. (*help\_ptr* - 1). They should be printed in reverse order, i.e., with *help\_line*[0] appearing last.

```

define hlp1 (#) ≡ help_line[0] ← #; end
define hlp2 (#) ≡ help_line[1] ← #; hlp1
define hlp3 (#) ≡ help_line[2] ← #; hlp2
define hlp4 (#) ≡ help_line[3] ← #; hlp3
define hlp5 (#) ≡ help_line[4] ← #; hlp4
define hlp6 (#) ≡ help_line[5] ← #; hlp5
define help0 ≡ help_ptr ← 0 { sometimes there might be no help }
define help1 ≡ begin help_ptr ← 1; hlp1 { use this with one help line }
define help2 ≡ begin help_ptr ← 2; hlp2 { use this with two help lines }
define help3 ≡ begin help_ptr ← 3; hlp3 { use this with three help lines }
define help4 ≡ begin help_ptr ← 4; hlp4 { use this with four help lines }
define help5 ≡ begin help_ptr ← 5; hlp5 { use this with five help lines }
define help6 ≡ begin help_ptr ← 6; hlp6 { use this with six help lines }

```

⟨ Global variables 13 ⟩ +≡

```

help_line: array [0 .. 5] of str_number; { helps for the next error }
help_ptr: 0 .. 6; { the number of help lines present }
use_err_help: boolean; { should the err_help list be shown? }

```

81. ⟨ Set initial values of key variables 21 ⟩ +≡

```

help_ptr ← 0; use_err_help ← false;

```

82. The *jump\_out* procedure just cuts across all active procedure levels and goes to *end\_of\_TEX*. This is the only nontrivial **goto** statement in the whole program. It is used when there is no recovery from a particular error.

Some Pascal compilers do not implement non-local **goto** statements. In such cases the body of *jump\_out* should simply be ‘*close\_files\_and\_terminate*;’ followed by a call on some system procedure that quietly terminates the program.

```

define do_final_end ≡
  begin update_terminal; ready_already ← 0;
  if (history ≠ spotless) ∧ (history ≠ warning_issued) then uexit(1)
  else uexit(0);
  end

```

⟨ Error handling procedures 79 ⟩ +≡

```

noreturn
procedure jump_out;
  begin close_files_and_terminate; do_final_end;
  end;

```

**83.** Here now is the general *error* routine.

⟨Error handling procedures 79⟩ +≡

```

procedure error; { completes the job of error reporting }
  label continue, exit;
  var c: ASCII_code; { what the user types }
      s1, s2, s3, s4: integer; { used to save global variables when deleting tokens }
  begin if history < error_message_issued then history ← error_message_issued;
  print_char("."); show_context;
  if (halt_on_error_p) then
    begin history ← fatal_error_stop; jump_out;
    end;
  if interaction = error_stop_mode then ⟨Get user's advice and return 84⟩;
  incr(error_count);
  if error_count = 100 then
    begin print_nl("(That_makes_100_errors;_please_try_again.)"); history ← fatal_error_stop;
    jump_out;
    end;
  ⟨Put help message on the transcript file 91⟩;
exit: end;

```

**84.** ⟨Get user's advice and **return** 84⟩ ≡

```

loop begin continue: clear_for_error_prompt; prompt_input("? ");
  if last = first then return;
  c ← buffer[first];
  if c ≥ "a" then c ← c + "A" - "a"; { convert to uppercase }
  ⟨Interpret code c and return if done 85⟩;
end

```

This code is used in section 83.

**85.** It is desirable to provide an ‘E’ option here that gives the user an easy way to return from TEX to the system editor, with the offending line ready to be edited. We do this by calling the external procedure *call\_edit* with a pointer to the filename, its length, and the line number. However, here we just set up the variables that will be used as arguments, since we don’t want to do the switch-to-editor until after TeX has closed its files.

There is a secret ‘D’ option available when the debugging routines haven’t been commented out.

```

define edit_file  $\equiv$  input_stack[base_ptr]
⟨Interpret code c and return if done 85⟩  $\equiv$ 
case c of
  "0", "1", "2", "3", "4", "5", "6", "7", "8", "9": if deletions_allowed then
    ⟨Delete c – "0" tokens and goto continue 89⟩;
debug "D": begin debug_help; goto continue; end; gubed
"E": if base_ptr > 0 then
  begin edit_name_start  $\leftarrow$  str_start[edit_file.name_field];
  edit_name_length  $\leftarrow$  str_start[edit_file.name_field + 1] – str_start[edit_file.name_field];
  edit_line  $\leftarrow$  line; jump_out;
  end;
"H": ⟨Print the help information and goto continue 90⟩;
"I": ⟨Introduce new material from the terminal and return 88⟩;
"Q", "R", "S": ⟨Change the interaction level and return 87⟩;
"X": begin interaction  $\leftarrow$  scroll_mode; jump_out;
  end;
othercases do_nothing
endcases;
⟨Print the menu of available options 86⟩

```

This code is used in section 84.

```

86. ⟨Print the menu of available options 86⟩  $\equiv$ 
begin print("Type<return>to proceed, S to scroll future error messages,");
print_nl("R to run without stopping, Q to run quietly,");
print_nl("I to insert something,");
if base_ptr > 0 then print("E to edit your file,");
if deletions_allowed then
  print_nl("1 or . . . or 9 to ignore the next 1 to 9 tokens of input,");
  print_nl("H for help, X to quit.");
end

```

This code is used in section 85.

**87.** Here the author of TEX apologizes for making use of the numerical relation between "Q", "R", "S", and the desired interaction settings *batch\_mode*, *nonstop\_mode*, *scroll\_mode*.

```

⟨Change the interaction level and return 87⟩  $\equiv$ 
begin error_count  $\leftarrow$  0; interaction  $\leftarrow$  batch_mode + c – "Q"; print("OK, entering");
case c of
  "Q": begin print_esc("batchmode"); decr(selector);
  end;
  "R": print_esc("nonstopmode");
  "S": print_esc("scrollmode");
end; {there are no other cases}
print("..."); print_ln; update_terminal; return;
end

```

This code is used in section 85.

**88.** When the following code is executed, *buffer*[(*first* + 1) .. (*last* - 1)] may contain the material inserted by the user; otherwise another prompt will be given. In order to understand this part of the program fully, you need to be familiar with T<sub>E</sub>X's input stacks.

```

⟨Introduce new material from the terminal and return 88⟩ ≡
  begin begin_file_reading; { enter a new syntactic level for terminal input }
    { now state = mid_line, so an initial blank space will count as a blank }
  if last > first + 1 then
    begin loc ← first + 1; buffer[first] ← " ";
    end
  else begin prompt_input("insert>"); loc ← first;
  end;
  first ← last; cur_input.limit_field ← last - 1; { no end_line_char ends this line }
  return;
end

```

This code is used in section 85.

**89.** We allow deletion of up to 99 tokens at a time.

```

⟨Delete c - "0" tokens and goto continue 89⟩ ≡
  begin s1 ← cur_tok; s2 ← cur_cmd; s3 ← cur_chr; s4 ← align_state; align_state ← 1000000;
  OK_to_interrupt ← false;
  if (last > first + 1) ∧ (buffer[first + 1] ≥ "0") ∧ (buffer[first + 1] ≤ "9") then
    c ← c * 10 + buffer[first + 1] - "0" * 11
  else c ← c - "0";
  while c > 0 do
    begin get_token; { one-level recursive call of error is possible }
    decr(c);
    end;
  cur_tok ← s1; cur_cmd ← s2; cur_chr ← s3; align_state ← s4; OK_to_interrupt ← true;
  help2("I_just_deleted_some_text,_as_you_asked.")
  ("You_cannot_delete_more,_or_insert,_or_whatever."); show_context; goto continue;
end

```

This code is used in section 85.

```

90. ⟨Print the help information and goto continue 90⟩ ≡
  begin if use_err_help then
    begin give_err_help; use_err_help ← false;
    end
  else begin if help_ptr = 0 then help2("Sorry,_I_dont_know_how_to_help_in_this_situation.")
    ("Maybe_you_should_try_asking_a_human?");
    repeat decr(help_ptr); print(help_line[help_ptr]); print_ln;
    until help_ptr = 0;
    end;
  help4("Sorry,_I_already_gave_what_help_I_could...")
  ("Maybe_you_should_try_asking_a_human?")
  ("An_error_might_have_occurred_before_I_noticed_any_problems.")
  ("``If_all_else_fails,_read_the_instructions.``");
  goto continue;
end

```

This code is used in section 85.

```

91. ⟨Put help message on the transcript file 91⟩ ≡
  if interaction > batch_mode then decr(selector); { avoid terminal output }
  if use_err_help then
    begin print_ln; give_err_help;
    end
  else while help_ptr > 0 do
    begin decr(help_ptr); print_nl(help_line[help_ptr]);
    end;
    print_ln;
  if interaction > batch_mode then incr(selector); { re-enable terminal output }
  print_ln

```

This code is used in section 83.

92. A dozen or so error messages end with a parenthesized integer, so we save a teeny bit of program space by declaring the following procedure:

```

procedure int_error(n : integer);
  begin print("□("); print_int(n); print_char(")"); error;
  end;

```

93. In anomalous cases, the print selector might be in an unknown state; the following subroutine is called to fix things just enough to keep running a bit longer.

```

procedure normalize_selector;
  begin if log_opened then selector ← term_and_log
  else selector ← term_only;
  if job_name = 0 then open_log_file;
  if interaction = batch_mode then decr(selector);
  end;

```

94. The following procedure prints T<sub>E</sub>X's last words before dying.

```

define succumb ≡
  begin if interaction = error_stop_mode then interaction ← scroll_mode;
    { no more interaction }
  if log_opened then error;
  debug if interaction > batch_mode then debug_help;
  gubed
  history ← fatal_error_stop; jump_out; { irrecoverable error }
  end

```

⟨Error handling procedures 79⟩ +≡

*noreturn*

```

procedure fatal_error(s : str_number); { prints s, and that's it }
  begin normalize_selector;
  print_err("Emergency□stop"); help1(s); succumb;
  end;

```

95. Here is the most dreaded error message.

```

⟨Error handling procedures 79⟩ +≡
  noreturn
procedure overflow(s : str_number; n : integer); { stop due to finiteness }
  begin normalize_selector; print_err("TEX_capacity_exceeded,_sorry_["; print(s); print_char("=");
  print_int(n); print_char("]"); help2("If_you_really_absolutely_need_more_capacity,")
  ("you_can_ask_a_wizard_to_enlarge_me."); succumb;
end;

```

96. The program might sometime run completely amok, at which point there is no choice but to stop. If no previous error has been detected, that's bad news; a message is printed that is really intended for the T<sub>E</sub>X maintenance person instead of the user (unless the user has been particularly diabolical). The index entries for 'this can't happen' may help to pinpoint the problem.

```

⟨Error handling procedures 79⟩ +≡
  noreturn
procedure confusion(s : str_number); { consistency check violated; s tells where }
begin normalize_selector;
if history < error_message_issued then
  begin print_err("This_can't_happen_["; print(s); print_char("]");
  help1("I'm_broken._Please_show_this_to_someone_who_can_fix_can_fix");
  end
else begin print_err("I_can't_go_on_meeting_you_like_this");
  help2("One_of_your_faux_pas_seems_to_have_wounded_me_deeply...")
  ("in_fact,_I'm_barely_conscious._Please_fix_it_and_try_again.");
  end;
  succumb;
end;

```

97. Users occasionally want to interrupt T<sub>E</sub>X while it's running. If the Pascal runtime system allows this, one can implement a routine that sets the global variable *interrupt* to some nonzero value when such an interrupt is signalled. Otherwise there is probably at least a way to make *interrupt* nonzero using the Pascal debugger.

```

define check_interrupt ≡
  begin if interrupt ≠ 0 then pause_for_instructions;
  end

```

```

⟨Global variables 13⟩ +≡
interrupt: integer; { should TEX pause for instructions? }
OK_to_interrupt: boolean; { should interrupts be observed? }

```

98. ⟨Set initial values of key variables 21⟩ +≡  
*interrupt* ← 0; *OK\_to\_interrupt* ← true;

99. When an interrupt has been detected, the program goes into its highest interaction level and lets the user have nearly the full flexibility of the *error* routine. TEX checks for interrupts only at times when it is safe to do this.

```

procedure pause_for_instructions;
  begin if OK_to_interrupt then
    begin interaction  $\leftarrow$  error_stop_mode;
    if (selector = log_only)  $\vee$  (selector = no_print) then incr(selector);
    print_err("Interruption"); help3("You_rang?")
    ("Try_to_insert_some_instructions_for_me_(e.g., `I\showlists`),")
    ("unless_you_just_want_to_quit_by_typing `X`."); deletions_allowed  $\leftarrow$  false; error;
    deletions_allowed  $\leftarrow$  true; interrupt  $\leftarrow$  0;
    end;
  end;

```

**100. Arithmetic with scaled dimensions.** The principal computations performed by T<sub>E</sub>X are done entirely in terms of integers less than  $2^{31}$  in magnitude; and divisions are done only when both dividend and divisor are nonnegative. Thus, the arithmetic specified in this program can be carried out in exactly the same way on a wide variety of computers, including some small ones. Why? Because the arithmetic calculations need to be spelled out precisely in order to guarantee that T<sub>E</sub>X will produce identical output on different machines. If some quantities were rounded differently in different implementations, we would find that line breaks and even page breaks might occur in different places. Hence the arithmetic of T<sub>E</sub>X has been designed with care, and systems that claim to be implementations of T<sub>E</sub>X82 should follow precisely the calculations as they appear in the present program.

(Actually there are three places where T<sub>E</sub>X uses **div** with a possibly negative numerator. These are harmless; see **div** in the index. Also if the user sets the `\time` or the `\year` to a negative value, some diagnostic information will involve negative-numerator division. The same remarks apply for **mod** as well as for **div**.)

**101.** Here is a routine that calculates half of an integer, using an unambiguous convention with respect to signed odd numbers.

```
function half(x : integer): integer;
  begin if odd(x) then half ← (x + 1) div 2
  else half ← x div 2;
  end;
```

**102.** Fixed-point arithmetic is done on *scaled integers* that are multiples of  $2^{-16}$ . In other words, a binary point is assumed to be sixteen bit positions from the right end of a binary computer word.

```
define unity ≡ '200000 {  $2^{16}$ , represents 1.00000 }
define two ≡ '400000 {  $2^{17}$ , represents 2.00000 }
```

⟨Types in the outer block 18) +≡

```
scaled = integer; { this type is used for scaled integers }
nonnegative_integer = 0 .. '177777777777; {  $0 \leq x < 2^{31}$  }
small_number = 0 .. 63; { this type is self-explanatory }
```

**103.** The following function is used to create a scaled integer from a given decimal fraction  $(.d_0d_1 \dots d_{k-1})$ , where  $0 \leq k \leq 17$ . The digit  $d_i$  is given in `dig[i]`, and the calculation produces a correctly rounded result.

```
function round_decimals(k : small_number): scaled; { converts a decimal fraction }
  var a: integer; { the accumulator }
  begin a ← 0;
  while k > 0 do
    begin decr(k); a ← (a + dig[k] * two) div 10;
    end;
  round_decimals ← (a + 1) div 2;
  end;
```

**104.** Conversely, here is a procedure analogous to *print\_int*. If the output of this procedure is subsequently read by TEX and converted by the *round\_decimals* routine above, it turns out that the original value will be reproduced exactly; the “simplest” such decimal number is output, but there is always at least one digit following the decimal point.

The invariant relation in the **repeat** loop is that a sequence of decimal digits yet to be printed will yield the original number if and only if they form a fraction  $f$  in the range  $s - \delta \leq 10 \cdot 2^{16} f < s$ . We can stop if and only if  $f = 0$  satisfies this condition; the loop will terminate before  $s$  can possibly become zero.

```

procedure print_scaled(s : scaled); { prints scaled real, rounded to five digits }
  var delta: scaled; { amount of allowable inaccuracy }
  begin if s < 0 then
    begin print_char("-"); negate(s); { print the sign, if negative }
    end;
    print_int(s div unity); { print the integer part }
    print_char("."); s ← 10 * (s mod unity) + 5; delta ← 10;
    repeat if delta > unity then s ← s + '100000 - 50000'; { round the last digit }
      print_char("0" + (s div unity)); s ← 10 * (s mod unity); delta ← delta * 10;
    until s ≤ delta;
  end;

```

**105.** Physical sizes that a TEX user specifies for portions of documents are represented internally as scaled points. Thus, if we define an ‘sp’ (scaled point) as a unit equal to  $2^{-16}$  printer’s points, every dimension inside of TEX is an integer number of sp. There are exactly 4,736,286.72 sp per inch. Users are not allowed to specify dimensions larger than  $2^{30} - 1$  sp, which is a distance of about 18.892 feet (5.7583 meters); two such quantities can be added without overflow on a 32-bit computer.

The present implementation of TEX does not check for overflow when dimensions are added or subtracted. This could be done by inserting a few dozen tests of the form ‘**if**  $x \geq '10000000000$  **then** *report\_overflow*’, but the chance of overflow is so remote that such tests do not seem worthwhile.

TEX needs to do only a few arithmetic operations on scaled quantities, other than addition and subtraction, and the following subroutines do most of the work. A single computation might use several subroutine calls, and it is desirable to avoid producing multiple error messages in case of arithmetic overflow; so the routines set the global variable *arith\_error* to *true* instead of reporting errors directly to the user. Another global variable, *remainder*, holds the remainder after a division.

```

define remainder ≡ tex_remainder

```

```

⟨ Global variables 13 ⟩ +≡

```

```

arith_error: boolean; { has arithmetic overflow occurred recently? }
remainder: scaled; { amount subtracted to get an exact division }

```

**106.** The first arithmetical subroutine we need computes  $nx + y$ , where  $x$  and  $y$  are *scaled* and  $n$  is an integer. We will also use it to multiply integers.

```

define nx_plus_y(#) ≡ mult_and_add(#, '7777777777')
define mult_integers(#) ≡ mult_and_add(#, 0, '1777777777')
function mult_and_add(n : integer; x, y, max_answer : scaled): scaled;
  begin if n < 0 then
    begin negate(x); negate(n);
    end;
  if n = 0 then mult_and_add ← y
  else if ((x ≤ (max_answer - y) div n) ∧ (-x ≤ (max_answer + y) div n)) then mult_and_add ← n * x + y
    else begin arith_error ← true; mult_and_add ← 0;
    end;
  end;

```

107. We also need to divide scaled dimensions by integers.

```

function x_over_n(x : scaled; n : integer): scaled;
  var negative: boolean; { should remainder be negated? }
  begin negative  $\leftarrow$  false;
  if n = 0 then
    begin arith_error  $\leftarrow$  true; x_over_n  $\leftarrow$  0; remainder  $\leftarrow$  x;
    end
  else begin if n < 0 then
    begin negate(x); negate(n); negative  $\leftarrow$  true;
    end;
    if x  $\geq$  0 then
      begin x_over_n  $\leftarrow$  x div n; remainder  $\leftarrow$  x mod n;
      end
    else begin x_over_n  $\leftarrow$  -((-x) div n); remainder  $\leftarrow$  -((-x) mod n);
    end;
  end;
  if negative then negate(remainder);
end;

```

108. Then comes the multiplication of a scaled number by a fraction  $n/d$ , where  $n$  and  $d$  are nonnegative integers  $\leq 2^{16}$  and  $d$  is positive. It would be too dangerous to multiply by  $n$  and then divide by  $d$ , in separate operations, since overflow might well occur; and it would be too inaccurate to divide by  $d$  and then multiply by  $n$ . Hence this subroutine simulates 1.5-precision arithmetic.

```

function xn_over_d(x : scaled; n, d : integer): scaled;
  var positive: boolean; { was x  $\geq$  0? }
  t, u, v: nonnegative_integer; { intermediate quantities }
  begin if x  $\geq$  0 then positive  $\leftarrow$  true
  else begin negate(x); positive  $\leftarrow$  false;
  end;
  t  $\leftarrow$  (x mod '100000) * n; u  $\leftarrow$  (x div '100000) * n + (t div '100000);
  v  $\leftarrow$  (u mod d) * '100000 + (t mod '100000);
  if u div d  $\geq$  '100000 then arith_error  $\leftarrow$  true
  else u  $\leftarrow$  '100000 * (u div d) + (v div d);
  if positive then
    begin xn_over_d  $\leftarrow$  u; remainder  $\leftarrow$  v mod d;
    end
  else begin xn_over_d  $\leftarrow$  -u; remainder  $\leftarrow$  -(v mod d);
  end;
end;

```

**109.** The next subroutine is used to compute the “badness” of glue, when a total  $t$  is supposed to be made from amounts that sum to  $s$ . According to *The T<sub>E</sub>Xbook*, the badness of this situation is  $100(t/s)^3$ ; however, badness is simply a heuristic, so we need not squeeze out the last drop of accuracy when computing it. All we really want is an approximation that has similar properties.

The actual method used to compute the badness is easier to read from the program than to describe in words. It produces an integer value that is a reasonably close approximation to  $100(t/s)^3$ , and all implementations of T<sub>E</sub>X should use precisely this method. Any badness of  $2^{13}$  or more is treated as infinitely bad, and represented by 10000.

It is not difficult to prove that

$$\text{badness}(t + 1, s) \geq \text{badness}(t, s) \geq \text{badness}(t, s + 1).$$

The badness function defined here is capable of computing at most 1095 distinct values, but that is plenty.

```

define inf_bad = 10000 { infinitely bad value }
function badness(t, s : scaled): halfword; { compute badness, given  $t \geq 0$  }
  var r: integer; { approximation to  $\alpha t/s$ , where  $\alpha^3 \approx 100 \cdot 2^{18}$  }
  begin if  $t = 0$  then badness  $\leftarrow$  0
  else if  $s \leq 0$  then badness  $\leftarrow$  inf_bad
    else begin if  $t \leq 7230584$  then  $r \leftarrow (t * 297) \text{ div } s$  {  $297^3 = 99.94 \times 2^{18}$  }
      else if  $s \geq 1663497$  then  $r \leftarrow t \text{ div } (s \text{ div } 297)$ 
        else  $r \leftarrow t$ ;
      if  $r > 1290$  then badness  $\leftarrow$  inf_bad {  $1290^3 < 2^{31} < 1291^3$  }
      else badness  $\leftarrow (r * r * r + '400000) \text{ div } '1000000$ ;
      end; { that was  $r^3/2^{18}$ , rounded to the nearest integer }
    end;

```

**110.** When T<sub>E</sub>X “packages” a list into a box, it needs to calculate the proportionality ratio by which the glue inside the box should stretch or shrink. This calculation does not affect T<sub>E</sub>X’s decision making, so the precise details of rounding, etc., in the glue calculation are not of critical importance for the consistency of results on different computers.

We shall use the type *glue\_ratio* for such proportionality ratios. A glue ratio should take the same amount of memory as an *integer* (usually 32 bits) if it is to blend smoothly with T<sub>E</sub>X’s other data structures. Thus *glue\_ratio* should be equivalent to *short\_real* in some implementations of Pascal. Alternatively, it is possible to deal with glue ratios using nothing but fixed-point arithmetic; see *TUGboat* **3**,1 (March 1982), 10–27. (But the routines cited there must be modified to allow negative glue ratios.)

```

define set_glue_ratio_zero(#)  $\equiv$  #  $\leftarrow$  0.0 { store the representation of zero ratio }
define set_glue_ratio_one(#)  $\equiv$  #  $\leftarrow$  1.0 { store the representation of unit ratio }
define float(#)  $\equiv$  # { convert from glue_ratio to type real }
define unfloat(#)  $\equiv$  # { convert from real to type glue_ratio }
define float_constant(#)  $\equiv$  #.0 { convert integer constant to real }

```

⟨Types in the outer block 18⟩  $\equiv$

**111. Packed data.** In order to make efficient use of storage space, T<sub>E</sub>X bases its major data structures on a *memory\_word*, which contains either a (signed) integer, possibly scaled, or a (signed) *glue\_ratio*, or a small number of fields that are one half or one quarter of the size used for storing integers.

If *x* is a variable of type *memory\_word*, it contains up to four fields that can be referred to as follows:

<i>x.int</i>	(an <i>integer</i> )
<i>x.sc</i>	(a <i>scaled integer</i> )
<i>x.gr</i>	(a <i>glue_ratio</i> )
<i>x.hh.lh</i> , <i>x.hh.rh</i>	(two halfword fields)
<i>x.hh.b0</i> , <i>x.hh.b1</i> , <i>x.hh.rh</i>	(two quarterword fields, one halfword field)
<i>x.qqqq.b0</i> , <i>x.qqqq.b1</i> , <i>x.qqqq.b2</i> , <i>x.qqqq.b3</i>	(four quarterword fields)

This is somewhat cumbersome to write, and not very readable either, but macros will be used to make the notation shorter and more transparent. The Pascal code below gives a formal definition of *memory\_word* and its subsidiary types, using packed variant records. T<sub>E</sub>X makes no assumptions about the relative positions of the fields within a word.

Since we are assuming 32-bit integers, a halfword must contain at least 16 bits, and a quarterword must contain at least 8 bits. But it doesn't hurt to have more bits; for example, with enough 36-bit words you might be able to have *mem\_max* as large as 262142, which is eight times as much memory as anybody had during the first four years of T<sub>E</sub>X's existence.

N.B.: Valuable memory space will be dreadfully wasted unless T<sub>E</sub>X is compiled by a Pascal that packs all of the *memory\_word* variants into the space of a single integer. This means, for example, that *glue\_ratio* words should be *short\_real* instead of *real* on some computers. Some Pascal compilers will pack an integer whose subrange is '0 .. 255' into an eight-bit field, but others insist on allocating space for an additional sign bit; on such systems you can get 256 values into a quarterword only if the subrange is '-128 .. 127'.

The present implementation tries to accommodate as many variations as possible, so it makes few assumptions. If integers having the subrange '*min\_quarterword* .. *max\_quarterword*' can be packed into a quarterword, and if integers having the subrange '*min\_halfword* .. *max\_halfword*' can be packed into a halfword, everything should work satisfactorily.

It is usually most efficient to have *min\_quarterword* = *min\_halfword* = 0, so one should try to achieve this unless it causes a severe problem. The values defined here are recommended for most 32-bit computers.

```

define min_quarterword = 0 {smallest allowable value in a quarterword }
define max_quarterword = 255 {largest allowable value in a quarterword }
define min_halfword ≡ -"FFFFFFF {smallest allowable value in a halfword }
define max_halfword ≡ "FFFFFFF {largest allowable value in a halfword }

```

**112.** Here are the inequalities that the quarterword and halfword values must satisfy (or rather, the inequalities that they mustn't satisfy):

(Check the "constant" values for consistency 14) +≡

```

init if (mem_min ≠ mem_bot) ∨ (mem_max ≠ mem_top) then bad ← 10;
tini
if (mem_min > mem_bot) ∨ (mem_max < mem_top) then bad ← 10;
if (min_quarterword > 0) ∨ (max_quarterword < 127) then bad ← 11;
if (min_halfword > 0) ∨ (max_halfword < 32767) then bad ← 12;
if (min_quarterword < min_halfword) ∨ (max_quarterword > max_halfword) then bad ← 13;
if (mem_bot - sup_main_memory < min_halfword) ∨ (mem_top + sup_main_memory ≥ max_halfword) ∨
(hi(0) ≠ 0) then bad ← 14;
if (max_font_max < min_halfword) ∨ (max_font_max > max_halfword) then bad ← 15;
if font_max > font_base + max_font_max then bad ← 16;
if (save_size > max_halfword) ∨ (max_strings > max_halfword) then bad ← 17;
if buf_size > max_halfword then bad ← 18;
if max_quarterword - min_quarterword < 255 then bad ← 19;

```

**113.** The operation of adding or subtracting *min\_quarterword* occurs quite frequently in TEX, so it is convenient to abbreviate this operation by using the macros *qi* and *qo* for input and output to and from quarterword format.

The inner loop of TEX will run faster with respect to compilers that don't optimize expressions like ' $x + 0$ ' and ' $x - 0$ ', if these macros are simplified in the obvious way when *min\_quarterword* = 0. So they have been simplified here in the obvious way.

The WEB source for TEX defines  $hi(\#) \equiv \# + min\_halfword$  which can be simplified when *min\_halfword* = 0. The Web2C implementation of TEX can use  $hi(\#) \equiv \#$  together with *min\_halfword* < 0 as long as *max\_halfword* is sufficiently large and this is required for pTEX.

```

define qi(#)  $\equiv$  # { to put an eight_bits item into a quarterword }
define qo(#)  $\equiv$  # { to take an eight_bits item from a quarterword }
define hi(#)  $\equiv$  # { to put a sixteen-bit item into a halfword }
define ho(#)  $\equiv$  # { to take a sixteen-bit item from a halfword }
define KANJI(#)  $\equiv$  # { pTeX: to output a KANJI code }
define tokenji(#)  $\equiv$  # { pTeX: to take a KANJI code from a halfword }
define tonum(#)  $\equiv$  # { pTeX: to put a KANJI code into a halfword }

```

**114.** The reader should study the following definitions closely:

```

define sc  $\equiv$  int { scaled data is equivalent to integer }
⟨Types in the outer block 18⟩  $\equiv$ 
quarterword = min_quarterword .. max_quarterword; halfword = min_halfword .. max_halfword;
two_choices = 1 .. 2; { used when there are two variants in a record }
four_choices = 1 .. 4; { used when there are four variants in a record }
 $\boxed{\#include\_ "texmfmem.h";}$  word_file = file of memory_word;

```

**115.** When debugging, we may want to print a *memory\_word* without knowing what type it is; so we print it in all modes.

```

debug procedure print_word(w : memory_word); { prints w in all ways }
begin print_int(w.int); print_char("□");
print_scaled(w.sc); print_char("□");
print_scaled(round(unity * float(w.gr))); print_ln;
print_int(w.hh.lh); print_char("="); print_int(w.hh.b0); print_char(":"); print_int(w.hh.b1);
print_char(";"); print_int(w.hh.rh); print_char("□");
print_int(w.qqqq.b0); print_char(":"); print_int(w.qqqq.b1); print_char(":"); print_int(w.qqqq.b2);
print_char(":"); print_int(w.qqqq.b3);
end;
gubed

```

**116. Dynamic memory allocation.** The T<sub>E</sub>X system does nearly all of its own memory allocation, so that it can readily be transported into environments that do not have automatic facilities for strings, garbage collection, etc., and so that it can be in control of what error messages the user receives. The dynamic storage requirements of T<sub>E</sub>X are handled by providing a large array *mem* in which consecutive blocks of words are used as nodes by the T<sub>E</sub>X routines.

Pointer variables are indices into this array, or into another array called *eqtb* that will be explained later. A pointer variable might also be a special flag that lies outside the bounds of *mem*, so we allow pointers to assume any *halfword* value. The minimum halfword value represents a null pointer. T<sub>E</sub>X does not assume that *mem*[*null*] exists.

```
define pointer ≡ halfword { a flag or a location in mem or eqtb }
define null ≡ min_halfword { the null pointer }
```

⟨Global variables 13⟩ +≡

```
temp_ptr: pointer; { a pointer variable for occasional emergency use }
```

**117.** The *mem* array is divided into two regions that are allocated separately, but the dividing line between these two regions is not fixed; they grow together until finding their “natural” size in a particular job. Locations less than or equal to *lo\_mem\_max* are used for storing variable-length records consisting of two or more words each. This region is maintained using an algorithm similar to the one described in exercise 2.5–19 of *The Art of Computer Programming*. However, no size field appears in the allocated nodes; the program is responsible for knowing the relevant size when a node is freed. Locations greater than or equal to *hi\_mem\_min* are used for storing one-word records; a conventional AVAIL stack is used for allocation in this region.

Locations of *mem* between *mem\_bot* and *mem\_top* may be dumped as part of preloaded format files, by the INITEX preprocessor. Production versions of T<sub>E</sub>X may extend the memory at both ends in order to provide more space; locations between *mem\_min* and *mem\_bot* are always used for variable-size nodes, and locations between *mem\_top* and *mem\_max* are always used for single-word nodes.

The key pointers that govern *mem* allocation have a prescribed order:

$$null \leq mem\_min \leq mem\_bot < lo\_mem\_max < hi\_mem\_min < mem\_top \leq mem\_end \leq mem\_max.$$

Empirical tests show that the present implementation of T<sub>E</sub>X tends to spend about 9% of its running time allocating nodes, and about 6% deallocating them after their use.

⟨Global variables 13⟩ +≡

```
yzmem: ↑memory_word; { the big dynamic storage area }
```

```
zmem: ↑memory_word; { the big dynamic storage area }
```

```
lo_mem_max: pointer; { the largest location of variable-size memory in use }
```

```
hi_mem_min: pointer; { the smallest location of one-word memory in use }
```

**118.** In order to study the memory requirements of particular applications, it is possible to prepare a version of T<sub>E</sub>X that keeps track of current and maximum memory usage. When code between the delimiters **stat** ... **tats** is not “commented out,” T<sub>E</sub>X will run a bit slower but it will report these statistics when *tracing\_stats* is sufficiently large.

⟨Global variables 13⟩ +≡

```
var_used, dyn_used: integer; { how much memory is in use }
```

**119.** Let's consider the one-word memory region first, since it's the simplest. The pointer variable *mem\_end* holds the highest-numbered location of *mem* that has ever been used. The free locations of *mem* that occur between *hi\_mem\_min* and *mem\_end*, inclusive, are of type *two\_halves*, and we write *info(p)* and *link(p)* for the *lh* and *rh* fields of *mem[p]* when it is of this type. The single-word free locations form a linked list

$$avail, link(avail), link(link(avail)), \dots$$

terminated by *null*.

```
define link(#)  $\equiv$  mem[#].hh.rh { the link field of a memory word }
define info(#)  $\equiv$  mem[#].hh.lh { the info field of a memory word }
```

$\langle$  Global variables 13  $\rangle$   $\equiv$

*avail*: pointer; { head of the list of available one-word nodes }

*mem\_end*: pointer; { the last one-word node used in *mem* }

**120.** If memory is exhausted, it might mean that the user has forgotten a right brace. We will define some procedures later that try to help pinpoint the trouble.

$\langle$  Declare the procedure called *show\_token\_list* 298  $\rangle$

$\langle$  Declare the procedure called *runaway* 312  $\rangle$

**121.** The function *get\_avail* returns a pointer to a new one-word node whose *link* field is null. However, TEX will halt if there is no more room left.

If the available-space list is empty, i.e., if *avail* = *null*, we try first to increase *mem\_end*. If that cannot be done, i.e., if *mem\_end* = *mem\_max*, we try to decrease *hi\_mem\_min*. If that cannot be done, i.e., if *hi\_mem\_min* = *lo\_mem\_max* + 1, we have to quit.

```
function get_avail: pointer; { single-word node allocation }
  var p: pointer; { the new node being got }
  begin p  $\leftarrow$  avail; { get top location in the avail stack }
  if p  $\neq$  null then avail  $\leftarrow$  link(avail) { and pop it off }
  else if mem_end < mem_max then { or go into virgin territory }
    begin incr(mem_end); p  $\leftarrow$  mem_end;
    end
  else begin decr(hi_mem_min); p  $\leftarrow$  hi_mem_min;
    if hi_mem_min  $\leq$  lo_mem_max then
      begin runaway; { if memory is exhausted, display possible runaway text }
      overflow("main_memory_size", mem_max + 1 - mem_min); { quit; all one-word nodes are busy }
      end;
    end;
  link(p)  $\leftarrow$  null; { provide an oft-desired initialization of the new node }
  stat incr(dyn_used); tats { maintain statistics }
  get_avail  $\leftarrow$  p;
end;
```

**122.** Conversely, a one-word node is recycled by calling *free\_avail*. This routine is part of TEX's "inner loop," so we want it to be fast.

```
define free_avail(#)  $\equiv$  { single-word node liberation }
  begin link(#)  $\leftarrow$  avail; avail  $\leftarrow$  #;
  stat decr(dyn_used); tats
  end
```

**123.** There's also a *fast\_get\_avail* routine, which saves the procedure-call overhead at the expense of extra programming. This routine is used in the places that would otherwise account for the most calls of *get\_avail*.

```

define fast_get_avail(#) ≡
  begin # ← avail; { avoid get_avail if possible, to save time }
  if # = null then # ← get_avail
  else begin avail ← link(#); link(#) ← null;
    stat incr(dyn_used); tats
  end;
end

```

**124.** The procedure *flush\_list*(*p*) frees an entire linked list of one-word nodes that starts at position *p*.

```

procedure flush_list(p : pointer); { makes list of single-word nodes available }
  var q, r: pointer; { list traversers }
  begin if p ≠ null then
    begin r ← p;
    repeat q ← r; r ← link(r);
      stat decr(dyn_used); tats
    until r = null; { now q is the last node on the list }
    link(q) ← avail; avail ← p;
  end;
end;

```

**125.** The available-space list that keeps track of the variable-size portion of *mem* is a nonempty, doubly-linked circular list of empty nodes, pointed to by the roving pointer *rover*.

Each empty node has size 2 or more; the first word contains the special value *max\_halfword* in its *link* field and the size in its *info* field; the second word contains the two pointers for double linking.

Each nonempty node also has size 2 or more. Its first word is of type *two\_halves*, and its *link* field is never equal to *max\_halfword*. Otherwise there is complete flexibility with respect to the contents of its other fields and its other words.

(We require *mem\_max* < *max\_halfword* because terrible things can happen when *max\_halfword* appears in the *link* field of a nonempty node.)

```

define empty_flag ≡ max_halfword { the link of an empty variable-size node }
define is_empty(#) ≡ (link(#) = empty_flag) { tests for empty node }
define node_size ≡ info { the size field in empty variable-size nodes }
define llink(#) ≡ info(# + 1) { left link in doubly-linked list of empty nodes }
define rlink(#) ≡ link(# + 1) { right link in doubly-linked list of empty nodes }

```

⟨ Global variables 13 ⟩ +≡

*rover*: *pointer*; { points to some node in the list of empties }

**126.** A call to *get\_node* with argument *s* returns a pointer to a new node of size *s*, which must be 2 or more. The *link* field of the first word of this new node is set to null. An overflow stop occurs if no suitable space exists.

If *get\_node* is called with  $s = 2^{30}$ , it simply merges adjacent free areas and returns the value *max\_halfword*.

```

function get_node(s : integer): pointer; { variable-size node allocation }
  label found, exit, restart;
  var p: pointer; { the node currently under inspection }
      q: pointer; { the node physically after node p }
      r: integer; { the newly allocated node, or a candidate for this honor }
      t: integer; { temporary register }
  begin restart: p ← rover; { start at some free node in the ring }
  repeat ⟨ Try to allocate within node p and its physical successors, and goto found if allocation was
    possible 128⟩;
    p ← rlink(p); { move to the next node in the ring }
  until p = rover; { repeat until the whole list has been traversed }
  if s = '1000000000' then
    begin get_node ← max_halfword; return;
    end;
  if lo_mem_max + 2 < hi_mem_min then
    if lo_mem_max + 2 ≤ mem_bot + max_halfword then
      ⟨ Grow more variable-size memory and goto restart 127⟩;
      overflow("main_memory_size", mem_max + 1 - mem_min); { sorry, nothing satisfactory is left }
    found: link(r) ← null; { this node is now nonempty }
    stat var_used ← var_used + s; { maintain usage statistics }
    tats
      get_node ← r;
    exit: end;

```

**127.** The lower part of *mem* grows by 1000 words at a time, unless we are very close to going under. When it grows, we simply link a new node into the available-space list. This method of controlled growth helps to keep the *mem* usage consecutive when TEX is implemented on “virtual memory” systems.

```

⟨ Grow more variable-size memory and goto restart 127⟩ ≡
  begin if hi_mem_min - lo_mem_max ≥ 1998 then t ← lo_mem_max + 1000
  else t ← lo_mem_max + 1 + (hi_mem_min - lo_mem_max) div 2; { lo_mem_max + 2 ≤ t < hi_mem_min }
  p ← llink(rover); q ← lo_mem_max; rlink(p) ← q; llink(rover) ← q;
  if t > mem_bot + max_halfword then t ← mem_bot + max_halfword;
  rlink(q) ← rover; llink(q) ← p; link(q) ← empty_flag; node_size(q) ← t - lo_mem_max;
  lo_mem_max ← t; link(lo_mem_max) ← null; info(lo_mem_max) ← null; rover ← q; goto restart;
  end

```

This code is used in section 126.

**128.** Empirical tests show that the routine in this section performs a node-merging operation about 0.75 times per allocation, on the average, after which it finds that  $r > p + 1$  about 95% of the time.

```

⟨ Try to allocate within node  $p$  and its physical successors, and goto found if allocation was possible 128 ⟩ ≡
   $q \leftarrow p + \text{node\_size}(p)$ ; { find the physical successor }
  while  $\text{is\_empty}(q)$  do { merge node  $p$  with node  $q$  }
    begin  $t \leftarrow \text{rlink}(q)$ ;
    if  $q = \text{rover}$  then  $\text{rover} \leftarrow t$ ;
     $\text{llink}(t) \leftarrow \text{llink}(q)$ ;  $\text{rlink}(\text{llink}(q)) \leftarrow t$ ;
     $q \leftarrow q + \text{node\_size}(q)$ ;
    end;
   $r \leftarrow q - s$ ;
  if  $r > \text{intcast}(p + 1)$  then ⟨ Allocate from the top of node  $p$  and goto found 129 ⟩;
  if  $r = p$  then
    if  $\text{rlink}(p) \neq p$  then ⟨ Allocate entire node  $p$  and goto found 130 ⟩;
     $\text{node\_size}(p) \leftarrow q - p$  { reset the size in case it grew }

```

This code is used in section 126.

```

129. ⟨ Allocate from the top of node  $p$  and goto found 129 ⟩ ≡
  begin  $\text{node\_size}(p) \leftarrow r - p$ ; { store the remaining size }
   $\text{rover} \leftarrow p$ ; { start searching here next time }
  goto found;
  end

```

This code is used in section 128.

**130.** Here we delete node  $p$  from the ring, and let  $\text{rover}$  rove around.

```

⟨ Allocate entire node  $p$  and goto found 130 ⟩ ≡
  begin  $\text{rover} \leftarrow \text{rlink}(p)$ ;  $t \leftarrow \text{llink}(p)$ ;  $\text{llink}(\text{rover}) \leftarrow t$ ;  $\text{rlink}(t) \leftarrow \text{rover}$ ; goto found;
  end

```

This code is used in section 128.

**131.** Conversely, when some variable-size node  $p$  of size  $s$  is no longer needed, the operation  $\text{free\_node}(p, s)$  will make its words available, by inserting  $p$  as a new empty node just before where  $\text{rover}$  now points.

```

procedure  $\text{free\_node}(p : \text{pointer}; s : \text{halfword})$ ; { variable-size node liberation }
  var  $q : \text{pointer}$ ; {  $\text{llink}(\text{rover})$  }
  begin  $\text{node\_size}(p) \leftarrow s$ ;  $\text{link}(p) \leftarrow \text{empty\_flag}$ ;  $q \leftarrow \text{llink}(\text{rover})$ ;  $\text{llink}(p) \leftarrow q$ ;  $\text{rlink}(p) \leftarrow \text{rover}$ ;
    { set both links }
   $\text{llink}(\text{rover}) \leftarrow p$ ;  $\text{rlink}(q) \leftarrow p$ ; { insert  $p$  into the ring }
  stat  $\text{var\_used} \leftarrow \text{var\_used} - s$ ; tats { maintain statistics }
  end;

```

**132.** Just before INITEX writes out the memory, it sorts the doubly linked available space list. The list is probably very short at such times, so a simple insertion sort is used. The smallest available location will be pointed to by *rover*, the next-smallest by *rlink(rover)*, etc.

```

init procedure sort_avail; { sorts the available variable-size nodes by location }
var p, q, r: pointer; { indices into mem }
      old_rover: pointer; { initial rover setting }
begin p ← get_node( '10000000000' ); { merge adjacent free areas }
      p ← rlink(rover); rlink(rover) ← max_halfword; old_rover ← rover;
      while p ≠ old_rover do ⟨ Sort p into the list starting at rover and advance p to rlink(p) 133 ⟩;
      p ← rover;
      while rlink(p) ≠ max_halfword do
        begin llink(rlink(p)) ← p; p ← rlink(p);
        end;
      rlink(p) ← rover; llink(rover) ← p;
end;
tini

```

**133.** The following **while** loop is guaranteed to terminate, since the list that starts at *rover* ends with *max\_halfword* during the sorting procedure.

⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink(p)* 133 ⟩ ≡

```

if p < rover then
  begin q ← p; p ← rlink(q); rlink(q) ← rover; rover ← q;
  end
else begin q ← rover;
  while rlink(q) < p do q ← rlink(q);
  r ← rlink(p); rlink(p) ← rlink(q); rlink(q) ← p; p ← r;
  end

```

This code is used in section 132.

**134. Data structures for boxes and their friends.** From the computer’s standpoint, T<sub>E</sub>X’s chief mission is to create horizontal and vertical lists. We shall now investigate how the elements of these lists are represented internally as nodes in the dynamic memory.

A horizontal or vertical list is linked together by *link* fields in the first word of each node. Individual nodes represent boxes, glue, penalties, or special things like discretionary hyphens; because of this variety, some nodes are longer than others, and we must distinguish different kinds of nodes. We do this by putting a ‘*type*’ field in the first word, together with the link and an optional ‘*subtype*’.

```
define type(#) ≡ mem[#].hh.b0  { identifies what kind of node this is }
define subtype(#) ≡ mem[#].hh.b1  { secondary identification in some cases }
```

**135.** A *char\_node*, which represents a single character, is the most important kind of node because it accounts for the vast majority of all boxes. Special precautions are therefore taken to ensure that a *char\_node* does not take up much memory space. Every such node is one word long, and in fact it is identifiable by this property, since other kinds of nodes have at least two words, and they appear in *mem* locations less than *hi\_mem\_min*. This makes it possible to omit the *type* field in a *char\_node*, leaving us room for two bytes that identify a *font* and a *character* within that font.

Note that the format of a *char\_node* allows for up to 256 different fonts and up to 256 characters per font; but most implementations will probably limit the total number of fonts to fewer than 75 per job, and most fonts will stick to characters whose codes are less than 128 (since higher codes are more difficult to access on most keyboards).

Extensions of T<sub>E</sub>X intended for oriental languages will need even more than 256 × 256 possible characters, when we consider different sizes and styles of type. It is suggested that Chinese and Japanese fonts be handled by representing such characters in two consecutive *char\_node* entries: The first of these has *font* = *font\_base*, and its *link* points to the second; the second identifies the font and the character dimensions. The saving feature about oriental characters is that most of them have the same box dimensions. The *character* field of the first *char\_node* is a “*charext*” that distinguishes between graphic symbols whose dimensions are identical for typesetting purposes. (See the METAFONT manual.) Such an extension of T<sub>E</sub>X would not be difficult; further details are left to the reader.

In order to make sure that the *character* code fits in a quarterword, T<sub>E</sub>X adds the quantity *min\_quarterword* to the actual code.

Character nodes appear only in horizontal lists, never in vertical lists.

```
define is_char_node(#) ≡ (# ≥ hi_mem_min)  { does the argument point to a char_node? }
define font ≡ type  { the font code in a char_node }
define character ≡ subtype  { the character code in a char_node }
```

**136.** An *hlist\_node* stands for a box that was made from a horizontal list. Each *hlist\_node* is seven words long, and contains the following fields (in addition to the mandatory *type* and *link*, which we shall not mention explicitly when discussing the other node types): The *height* and *width* and *depth* are scaled integers denoting the dimensions of the box. There is also a *shift\_amount* field, a scaled integer indicating how much this box should be lowered (if it appears in a horizontal list), or how much it should be moved to the right (if it appears in a vertical list). There is a *list\_ptr* field, which points to the beginning of the list from which this box was fabricated; if *list\_ptr* is *null*, the box is empty. Finally, there are three fields that represent the setting of the glue: *glue\_set(p)* is a word of type *glue\_ratio* that represents the proportionality constant for glue setting; *glue\_sign(p)* is *stretching* or *shrinking* or *normal* depending on whether or not the glue should stretch or shrink or remain rigid; and *glue\_order(p)* specifies the order of infinity to which glue setting applies (*normal*, *fil*, *fill*, or *filll*). The *subtype* field is not used in TEX. In pTEX the *subtype* field records the box direction *box\_dir*.

```

define hlist_node = 0 { type of hlist nodes }
define box_node_size = 8 { number of words to allocate for a box node }
define box_dir(#) ≡ (qo(subtype(#))) { direction of a box }
define set_box_dir(#) ≡ subtype(#) ← set_box_dir_end
define set_box_dir_end(#) ≡ qi(#)

define dir_default = 0 { direction of the box, default Left to Right }
define dir_dtou = 1 { direction of the box, Bottom to Top }
define dir_tate = 3 { direction of the box, Top to Bottom }
define dir_yoko = 4 { direction of the box, equal default }
define any_dir ≡ dir_yoko, dir_tate, dir_dtou

define width_offset = 1 { position of width field in a box node }
define depth_offset = 2 { position of depth field in a box node }
define height_offset = 3 { position of height field in a box node }
define width(#) ≡ mem[# + width_offset].sc { width of the box, in sp }
define depth(#) ≡ mem[# + depth_offset].sc { depth of the box, in sp }
define height(#) ≡ mem[# + height_offset].sc { height of the box, in sp }
define shift_amount(#) ≡ mem[# + 4].sc { repositioning distance, in sp }
define list_offset = 5 { position of list_ptr field in a box node }
define list_ptr(#) ≡ link(# + list_offset) { beginning of the list inside the box }
define glue_order(#) ≡ subtype(# + list_offset) { applicable order of infinity }
define glue_sign(#) ≡ type(# + list_offset) { stretching or shrinking }
define normal = 0 { the most common case when several cases are named }
define stretching = 1 { glue setting applies to the stretch components }
define shrinking = 2 { glue setting applies to the shrink components }
define glue_offset = 6 { position of glue_set in a box node }
define glue_set(#) ≡ mem[# + glue_offset].gr { a word of type glue_ratio for glue setting }
define space_offset = 7 { position of glue_set in a box node }
define space_ptr(#) ≡ link(# + space_offset)
define xspace_ptr(#) ≡ info(# + space_offset)

```

**137.** The *new\_null\_box* function returns a pointer to an *hlist\_node* in which all subfields have the values corresponding to ‘\hbox{’}. The *subtype* field is set to *min\_quarterword*, since that’s the desired *span\_count* value if this *hlist\_node* is changed to an *unset\_node*.

```
function new_null_box: pointer; { creates a new box node }
  var p: pointer; { the new node }
  begin p ← get_node(box_node_size); type(p) ← hlist_node; subtype(p) ← min_quarterword;
  width(p) ← 0; depth(p) ← 0; height(p) ← 0; shift_amount(p) ← 0; list_ptr(p) ← null;
  glue_sign(p) ← normal; glue_order(p) ← normal; set_glue_ratio_zero(glue_set(p));
  space_ptr(p) ← zero_glue; xspace_ptr(p) ← zero_glue; add_glue_ref(zero_glue); add_glue_ref(zero_glue);
  new_null_box ← p;
end;
```

**138.** A *vlist\_node* is like an *hlist\_node* in all respects except that it contains a vertical list.

```
define vlist_node = 1 { type of vlist nodes }
```

**139.** A *dir\_node* stands for direction change.

```
define dir_node = 2 { type of dir nodes }
```

```
function new_dir_node(b: pointer; dir: eight_bits): pointer;
  var p: pointer; { the new node }
  begin if type(b) > vlist_node then confusion("new_dir_node: not_box");
  p ← new_null_box; type(p) ← dir_node; set_box_dir(p)(dir);
  case box_dir(b) of
  dir_yoko: ⟨Yoko to other direction 140⟩;
  dir_tate: ⟨Tate to other direction 141⟩;
  dir_dtou: ⟨DtoU to other direction 142⟩;
  othercases confusion("new_dir_node: illegal_dir");
  endcases; link(b) ← null; list_ptr(p) ← b; new_dir_node ← p;
end;
```

**140.** ⟨Yoko to other direction 140⟩ ≡

```
case dir of
  dir_tate: begin width(p) ← height(b) + depth(b); depth(p) ← width(b)/2;
  height(p) ← width(b) - depth(p);
  end;
  dir_dtou: begin width(p) ← height(b) + depth(b); depth(p) ← 0; height(p) ← width(b);
  end;
  othercases confusion("new_dir_node: y->?");
endcases
```

This code is used in section 139.

**141.** ⟨Tate to other direction 141⟩ ≡

```
case dir of
  dir_yoko: begin width(p) ← height(b) + depth(b); depth(p) ← 0; height(p) ← width(b);
  end;
  dir_dtou: begin width(p) ← width(b); depth(p) ← height(b); height(p) ← depth(b);
  end;
  othercases confusion("new_dir_node: t->?");
endcases
```

This code is used in section 139.

142.  $\langle \text{DtoU to other direction } 142 \rangle \equiv$

```

case dir of
  dir_yoko: begin width(p)  $\leftarrow$  height(b) + depth(b); depth(p)  $\leftarrow$  0; height(p)  $\leftarrow$  width(b);
    end;
  dir_tate: begin width(p)  $\leftarrow$  width(b); depth(p)  $\leftarrow$  height(b); height(p)  $\leftarrow$  depth(b);
    end;
othercases confusion("new_dir_node:d->?");
endcases

```

This code is used in section 139.

143. A *rule\_node* stands for a solid black rectangle; it has *width*, *depth*, and *height* fields just as in an *hlist\_node*. However, if any of these dimensions is  $-2^{30}$ , the actual value will be determined by running the rule up to the boundary of the innermost enclosing box. This is called a “running dimension.” The *width* is never running in an *hlist*; the *height* and *depth* are never running in a *vlist*.

```

define rule_node = 3 { type of rule nodes }
define rule_node_size = 4 { number of words to allocate for a rule node }
define null_flag  $\equiv$   $-2^{30}$  {  $-2^{30}$ , signifies a missing item }
define is_running(#)  $\equiv$  (# = null_flag) { tests for a running dimension }

```

144. A new rule node is delivered by the *new\_rule* function. It makes all the dimensions “running,” so you have to change the ones that are not allowed to run.

```

function new_rule: pointer;
  var p: pointer; { the new node }
  begin p  $\leftarrow$  get_node(rule_node_size); type(p)  $\leftarrow$  rule_node; subtype(p)  $\leftarrow$  0; { the subtype is not used }
  width(p)  $\leftarrow$  null_flag; depth(p)  $\leftarrow$  null_flag; height(p)  $\leftarrow$  null_flag; new_rule  $\leftarrow$  p;
  end;

```

145. Insertions are represented by *ins\_node* records, where the *subtype* indicates the corresponding box number. For example, ‘\insert 250’ leads to an *ins\_node* whose *subtype* is  $250 + \text{min\_quarterword}$ . The *height* field of an *ins\_node* is slightly misnamed; it actually holds the natural height plus depth of the vertical list being inserted. The *depth* field holds the *split\_max\_depth* to be used in case this insertion is split, and the *split\_top\_ptr* points to the corresponding *split\_top\_skip*. The *float\_cost* field holds the *floating\_penalty* that will be used if this insertion floats to a subsequent page after a split insertion of the same class. There is one more field, the *ins\_ptr*, which points to the beginning of the *vlist* for the insertion.

```

define ins_node = 4 { type of insertion nodes }
define ins_node_size = 6 { number of words to allocate for an insertion }
define float_cost(#)  $\equiv$  mem[# + 1].int { the floating_penalty to be used }
define ins_ptr(#)  $\equiv$  info(# + 4) { the vertical list to be inserted }
define split_top_ptr(#)  $\equiv$  link(# + 4) { the split_top_skip to be used }
define ins_dir(#)  $\equiv$  subtype(# + 5) { direction of ins_node }

```

146. A *disp\_node* has a *disp\_dimen* field that points to the displacement distance of the baselineshift between Latin characters and Kanji characters.

```

define disp_node = 5 { type of a displace node }
define disp_dimen(#)  $\equiv$  mem[# + 1].sc

```

**147.** A *mark\_node* has a *mark\_ptr* field that points to the reference count of a token list that contains the user's `\mark` text. This field occupies a full word instead of a halfword, because there's nothing to put in the other halfword; it is easier in Pascal to use the full word than to risk leaving garbage in the unused half.

```
define mark_node = 6 { type of a mark node }
define small_node_size = 2 { number of words to allocate for most node types }
define mark_ptr(#) ≡ mem[# + 1].int { head of the token list for a mark }
```

**148.** An *adjust\_node*, which occurs only in horizontal lists, specifies material that will be moved out into the surrounding vertical list; i.e., it is used to implement T<sub>E</sub>X's '`\adjust`' operation. The *adjust\_ptr* field points to the vlist containing this material.

```
define adjust_node = 7 { type of an adjust node }
define adjust_ptr ≡ mark_ptr { vertical list to be moved out of horizontal list }
```

**149.** A *ligature\_node*, which occurs only in horizontal lists, specifies a character that was fabricated from the interaction of two or more actual characters. The second word of the node, which is called the *lig\_char* word, contains *font* and *character* fields just as in a *char\_node*. The characters that generated the ligature have not been forgotten, since they are needed for diagnostic messages and for hyphenation; the *lig\_ptr* field points to a linked list of character nodes for all original characters that have been deleted. (This list might be empty if the characters that generated the ligature were retained in other nodes.)

The *subtype* field is 0, plus 2 and/or 1 if the original source of the ligature included implicit left and/or right boundaries.

```
define ligature_node = 8 { type of a ligature node }
define lig_char(#) ≡ # + 1 { the word where the ligature is to be found }
define lig_ptr(#) ≡ link(lig_char(#)) { the list of characters }
```

**150.** The *new\_ligature* function creates a ligature node having given contents of the *font*, *character*, and *lig\_ptr* fields. We also have a *new\_lig\_item* function, which returns a two-word node having a given *character* field. Such nodes are used for temporary processing as ligatures are being created.

```
function new_ligature(f : internal_font_number; c : quarterword; q : pointer): pointer;
var p : pointer; { the new node }
begin p ← get_node(small_node_size); type(p) ← ligature_node; font(lig_char(p)) ← f;
character(lig_char(p)) ← c; lig_ptr(p) ← q; subtype(p) ← 0; new_ligature ← p;
end;

function new_lig_item(c : quarterword): pointer;
var p : pointer; { the new node }
begin p ← get_node(small_node_size); character(p) ← c; lig_ptr(p) ← null; new_lig_item ← p;
end;
```

**151.** A *disc\_node*, which occurs only in horizontal lists, specifies a “discretionary” line break. If such a break occurs at node *p*, the text that starts at *pre\_break(p)* will precede the break, the text that starts at *post\_break(p)* will follow the break, and text that appears in the next *replace\_count(p)* nodes will be ignored. For example, an ordinary discretionary hyphen, indicated by ‘\-', yields a *disc\_node* with *pre\_break* pointing to a *char\_node* containing a hyphen, *post\_break* = *null*, and *replace\_count* = 0. All three of the discretionary texts must be lists that consist entirely of character, kern, box, rule, and ligature nodes.

If *pre\_break(p)* = *null*, the *ex.hyphen\_penalty* will be charged for this break. Otherwise the *hyphen\_penalty* will be charged. The texts will actually be substituted into the list by the line-breaking algorithm if it decides to make the break, and the discretionary node will disappear at that time; thus, the output routine sees only discretionaries that were not chosen.

```

define disc_node = 9 { type of a discretionary node }
define replace_count ≡ subtype { how many subsequent nodes to replace }
define pre_break ≡ llink { text that precedes a discretionary break }
define post_break ≡ rlink { text that follows a discretionary break }
function new_disc: pointer; { creates an empty disc_node }
  var p: pointer; { the new node }
  begin p ← get_node(small_node_size); type(p) ← disc_node; replace_count(p) ← 0; pre_break(p) ← null;
  post_break(p) ← null; new_disc ← p;
  end;

```

**152.** A *whatsit\_node* is a wild card reserved for extensions to T<sub>E</sub>X. The *subtype* field in its first word says what ‘*whatsit*’ it is, and implicitly determines the node size (which must be 2 or more) and the format of the remaining words. When a *whatsit\_node* is encountered in a list, special actions are invoked; knowledgeable people who are careful not to mess up the rest of T<sub>E</sub>X are able to make T<sub>E</sub>X do new things by adding code at the end of the program. For example, there might be a ‘T<sub>E</sub>Xnicolor’ extension to specify different colors of ink, and the *whatsit\_node* might contain the desired parameters.

The present implementation of T<sub>E</sub>X treats the features associated with ‘\write’ and ‘\special’ as if they were extensions, in order to illustrate how such routines might be coded. We shall defer further discussion of extensions until the end of this program.

```

define whatsit_node = 10 { type of special extension nodes }

```

**153.** A *math\_node*, which occurs only in horizontal lists, appears before and after mathematical formulas. The *subtype* field is *before* before the formula and *after* after it. There is a *width* field, which represents the amount of surrounding space inserted by `\mathsurround`.

```

define math_node = 11 { type of a math node }
define before = 0 { subtype for math node that introduces a formula }
define after = 1 { subtype for math node that winds up a formula }
function new_math(w: scaled; s: small_number): pointer;
  var p: pointer; { the new node }
  begin p ← get_node(small_node_size); type(p) ← math_node; subtype(p) ← s; width(p) ← w;
  new_math ← p;
  end;

```

**154.** T<sub>E</sub>X makes use of the fact that *hlist\_node*, *vlist\_node*, *rule\_node*, *ins\_node*, *mark\_node*, *adjust\_node*, *ligature\_node*, *disc\_node*, *whatsit\_node*, and *math\_node* are at the low end of the type codes, by permitting a break at glue in a list if and only if the *type* of the previous node is less than *math\_node*. Furthermore, a node is discarded after a break if its type is *math\_node* or more.

```

define precedes_break(#) ≡ (type(#) < math_node)
define non_discardable(#) ≡ (type(#) < math_node)

```

**155.** A *glue\_node* represents glue in a list. However, it is really only a pointer to a separate glue specification, since T<sub>E</sub>X makes use of the fact that many essentially identical nodes of glue are usually present. If *p* points to a *glue\_node*, *glue\_ptr(p)* points to another packet of words that specify the stretch and shrink components, etc.

Glue nodes also serve to represent leaders; the *subtype* is used to distinguish between ordinary glue (which is called *normal*) and the three kinds of leaders (which are called *a\_leaders*, *c\_leaders*, and *x\_leaders*). The *leader\_ptr* field points to a rule node or to a box node containing the leaders; it is set to *null* in ordinary glue nodes.

Many kinds of glue are computed from T<sub>E</sub>X's "skip" parameters, and it is helpful to know which parameter has led to a particular glue node. Therefore the *subtype* is set to indicate the source of glue, whenever it originated as a parameter. We will be defining symbolic names for the parameter numbers later (e.g., *line\_skip\_code* = 0, *baseline\_skip\_code* = 1, etc.); it suffices for now to say that the *subtype* of parametric glue will be the same as the parameter number, plus one.

In math formulas there are two more possibilities for the *subtype* in a glue node: *mu\_glue* denotes an `\mskip` (where the units are scaled mu instead of scaled pt); and *cond\_math\_glue* denotes the '`\nonscript`' feature that cancels the glue node immediately following if it appears in a subscript.

```

define glue_node = 12  { type of node that points to a glue specification }
define cond_math_glue = 98  { special subtype to suppress glue in the next node }
define mu_glue = 99  { subtype for math glue }
define a_leaders = 100  { subtype for aligned leaders }
define c_leaders = 101  { subtype for centered leaders }
define x_leaders = 102  { subtype for expanded leaders }
define glue_ptr ≡ llink  { pointer to a glue specification }
define leader_ptr ≡ rlink  { pointer to box or rule node for leaders }

```

**156.** A glue specification has a halfword reference count in its first word, representing *null* plus the number of glue nodes that point to it (less one). Note that the reference count appears in the same position as the *link* field in list nodes; this is the field that is initialized to *null* when a node is allocated, and it is also the field that is flagged by *empty\_flag* in empty nodes.

Glue specifications also contain three *scaled* fields, for the *width*, *stretch*, and *shrink* dimensions. Finally, there are two one-byte fields called *stretch\_order* and *shrink\_order*; these contain the orders of infinity (*normal*, *fil*, *fill*, or *filll*) corresponding to the stretch and shrink values.

```

define glue_spec_size = 4  { number of words to allocate for a glue specification }
define glue_ref_count( # ) ≡ link( # )  { reference count of a glue specification }
define stretch( # ) ≡ mem[ # + 2 ].sc  { the stretchability of this glob of glue }
define shrink( # ) ≡ mem[ # + 3 ].sc  { the shrinkability of this glob of glue }
define stretch_order ≡ type  { order of infinity for stretching }
define shrink_order ≡ subtype  { order of infinity for shrinking }
define fil = 1  { first-order infinity }
define fill = 2  { second-order infinity }
define filll = 3  { third-order infinity }

```

⟨Types in the outer block 18⟩ +≡

```

glue_ord = normal .. filll;  { infinity to the 0, 1, 2, or 3 power }

```

**157.** Here is a function that returns a pointer to a copy of a glue spec. The reference count in the copy is *null*, because there is assumed to be exactly one reference to the new specification.

```
function new_spec(p : pointer): pointer; { duplicates a glue specification }
  var q: pointer; { the new spec }
  begin q ← get_node(glue_spec_size);
  mem[q] ← mem[p]; glue_ref_count(q) ← null;
  width(q) ← width(p); stretch(q) ← stretch(p); shrink(q) ← shrink(p); new_spec ← q;
  end;
```

**158.** And here's a function that creates a glue node for a given parameter identified by its code number; for example, *new\_param\_glue*(*line\_skip\_code*) returns a pointer to a glue node for the current `\lineskip`.

```
function new_param_glue(n : small_number): pointer;
  var p: pointer; { the new node }
  q: pointer; { the glue specification }
  begin p ← get_node(small_node_size); type(p) ← glue_node; subtype(p) ← n + 1; leader_ptr(p) ← null;
  q ← ⟨ Current mem equivalent of glue parameter number n 230 ⟩; glue_ptr(p) ← q;
  incr(glue_ref_count(q)); new_param_glue ← p;
  end;
```

**159.** Glue nodes that are more or less anonymous are created by *new\_glue*, whose argument points to a glue specification.

```
function new_glue(q : pointer): pointer;
  var p: pointer; { the new node }
  begin p ← get_node(small_node_size); type(p) ← glue_node; subtype(p) ← normal;
  leader_ptr(p) ← null; glue_ptr(p) ← q; incr(glue_ref_count(q)); new_glue ← p;
  end;
```

**160.** Still another subroutine is needed: This one is sort of a combination of *new\_param\_glue* and *new\_glue*. It creates a glue node for one of the current glue parameters, but it makes a fresh copy of the glue specification, since that specification will probably be subject to change, while the parameter will stay put. The global variable *temp\_ptr* is set to the address of the new spec.

```
function new_skip_param(n : small_number): pointer;
  var p: pointer; { the new node }
  begin temp_ptr ← new_spec(⟨ Current mem equivalent of glue parameter number n 230 ⟩);
  p ← new_glue(temp_ptr); glue_ref_count(temp_ptr) ← null; subtype(p) ← n + 1; new_skip_param ← p;
  end;
```

**161.** A *kern\_node* has a *width* field to specify a (normally negative) amount of spacing. This spacing correction appears in horizontal lists between letters like A and V when the font designer said that it looks better to move them closer together or further apart. A kern node can also appear in a vertical list, when its '*width*' denotes additional spacing in the vertical direction. The *subtype* is either *normal* (for kerns inserted from font information or math mode calculations) or *explicit* (for kerns inserted from `\kern` and `\/` commands) or *acc\_kern* (for kerns inserted from non-math accents) or *mu\_glue* (for kerns inserted from `\mkern` specifications in math formulas).

```
define kern_node = 13 { type of a kern node }
define explicit = 1 { subtype of kern nodes from \kern }
define acc_kern = 2 { subtype of kern nodes from accents }
define ita_kern = 3 { subtype of kern nodes from \/ }
```

**162.** The *new\_kern* function creates a kern node having a given width.

```
function new_kern(w : scaled): pointer;
  var p: pointer; { the new node }
  begin p ← get_node(small_node_size); type(p) ← kern_node; subtype(p) ← normal; width(p) ← w;
  new_kern ← p;
end;
```

**163.** A *penalty\_node* specifies the penalty associated with line or page breaking, in its *penalty* field. This field is a fullword integer, but the full range of integer values is not used: Any penalty  $\geq 10000$  is treated as infinity, and no break will be allowed for such high values. Similarly, any penalty  $\leq -10000$  is treated as negative infinity, and a break will be forced.

```
define penalty_node = 14 { type of a penalty node }
define widow_pena = 1 { subtype of penalty nodes from \jchridowpenalty }
define kinsoku_pena = 2 { subtype of penalty nodes from kinsoku }
define inf_penalty = inf_bad { “infinite” penalty value }
define eject_penalty = -inf_penalty { “negatively infinite” penalty value }
define penalty(#) ≡ mem[# + 1].int { the added cost of breaking a list here }
```

**164.** Anyone who has been reading the last few sections of the program will be able to guess what comes next.

```
function new_penalty(m : integer): pointer;
  var p: pointer; { the new node }
  begin p ← get_node(small_node_size); type(p) ← penalty_node; subtype(p) ← 0;
  { the subtype is not used }
  penalty(p) ← m; new_penalty ← p;
end;
```

**165.** You might think that we have introduced enough node types by now. Well, almost, but there is one more: An *unset\_node* has nearly the same format as an *hlist\_node* or *vlist\_node*; it is used for entries in `\halign` or `\valign` that are not yet in their final form, since the box dimensions are their “natural” sizes before any glue adjustment has been made. The *glue\_set* word is not present; instead, we have a *glue\_stretch* field, which contains the total stretch of order *glue\_order* that is present in the *hlist* or *vlist* being boxed. Similarly, the *shift\_amount* field is replaced by a *glue\_shrink* field, containing the total shrink of order *glue\_sign* that is present. The *subtype* field is called *span\_count*; an *unset* box typically contains the data for  $qo(\text{span\_count}) + 1$  columns. *Unset* nodes will be changed to *box* nodes when alignment is completed.

```
define unset_node = 15 { type for an unset node }
define glue_stretch(#) ≡ mem[# + glue_offset].sc { total stretch in an unset node }
define glue_shrink ≡ shift_amount { total shrink in an unset node }
define span_count ≡ subtype { indicates the number of spanned columns }
```

**166.** In fact, there are still more types coming. When we get to math formula processing we will see that a *style\_node* has *type* = 16; and a number of larger type codes will also be defined, for use in math mode only.

**167.** Warning: If any changes are made to these data structure layouts, such as changing any of the node sizes or even reordering the words of nodes, the *copy\_node\_list* procedure and the memory initialization code below may have to be changed. Such potentially dangerous parts of the program are listed in the index under ‘data structure assumptions’. However, other references to the nodes are made symbolically in terms of the `WEB` macro definitions above, so that format changes will leave T<sub>E</sub>X’s other algorithms intact.

**168. Memory layout.** Some areas of *mem* are dedicated to fixed usage, since static allocation is more efficient than dynamic allocation when we can get away with it. For example, locations *mem\_bot* to *mem\_bot* + 3 are always used to store the specification for glue that is ‘Opt plus Opt minus Opt’. The following macro definitions accomplish the static allocation by giving symbolic names to the fixed positions. Static variable-size nodes appear in locations *mem\_bot* through *lo\_mem\_stat\_max*, and static single-word nodes appear in locations *hi\_mem\_stat\_min* through *mem\_top*, inclusive. It is harmless to let *lig\_trick* and *garbage* share the same location of *mem*.

```

define zero_glue ≡ mem_bot { specification for Opt plus Opt minus Opt }
define fil_glue ≡ zero_glue + glue_spec_size { Opt plus 1fil minus Opt }
define fill_glue ≡ fil_glue + glue_spec_size { Opt plus 1fill minus Opt }
define ss_glue ≡ fill_glue + glue_spec_size { Opt plus 1fil minus 1fil }
define fil_neg_glue ≡ ss_glue + glue_spec_size { Opt plus -1fil minus Opt }
define lo_mem_stat_max ≡ fil_neg_glue + glue_spec_size - 1
    { largest statically allocated word in the variable-size mem }

define page_ins_head ≡ mem_top { list of insertion data for current page }
define contrib_head ≡ mem_top - 1 { vlist of items not yet on current page }
define page_head ≡ mem_top - 2 { vlist for current page }
define temp_head ≡ mem_top - 3 { head of a temporary list of some kind }
define hold_head ≡ mem_top - 4 { head of a temporary list of another kind }
define adjust_head ≡ mem_top - 5 { head of adjustment list returned by hpack }
define active ≡ mem_top - 7 { head of active list in line_break, needs two words }
define align_head ≡ mem_top - 8 { head of preamble list for alignments }
define end_span ≡ mem_top - 9 { tail of spanned-width lists }
define omit_template ≡ mem_top - 10 { a constant token list }
define null_list ≡ mem_top - 11 { permanently empty list }
define lig_trick ≡ mem_top - 12 { a ligature masquerading as a char_node }
define garbage ≡ mem_top - 12 { used for scrap information }
define backup_head ≡ mem_top - 13 { head of token list built by scan_keyword }
define hi_mem_stat_min ≡ mem_top - 13 { smallest statically allocated word in the one-word mem }
define hi_mem_stat_usage = 14 { the number of one-word nodes always present }

```

**169.** The following code gets *mem* off to a good start, when T<sub>E</sub>X is initializing itself the slow way.

```

⟨Local variables for initialization 19⟩ +≡
k: integer; { index into mem, eqtb, etc. }

```

```

170.  ⟨ Initialize table entries (done by INITEX only) 170 ⟩ ≡
for k ← mem_bot + 1 to lo_mem_stat_max do mem[k].sc ← 0; { all glue dimensions are zeroed }
k ← mem_bot; while k ≤ lo_mem_stat_max do { set first words of glue specifications }
  begin glue_ref_count(k) ← null + 1; stretch_order(k) ← normal; shrink_order(k) ← normal;
  k ← k + glue_spec_size;
  end;
stretch(fil_glue) ← unity; stretch_order(fil_glue) ← fil;
stretch(fill_glue) ← unity; stretch_order(fill_glue) ← fill;
stretch(ss_glue) ← unity; stretch_order(ss_glue) ← fil;
shrink(ss_glue) ← unity; shrink_order(ss_glue) ← fil;
stretch(fil_neg_glue) ← -unity; stretch_order(fil_neg_glue) ← fil;
rover ← lo_mem_stat_max + 1; link(rover) ← empty_flag; { now initialize the dynamic memory }
node_size(rover) ← 1000; { which is a 1000-word available node }
llink(rover) ← rover; rlink(rover) ← rover;
lo_mem_max ← rover + 1000; link(lo_mem_max) ← null; info(lo_mem_max) ← null;
for k ← hi_mem_stat_min to mem_top do mem[k] ← mem[lo_mem_max]; { clear list heads }
⟨ Initialize the special list heads and constant nodes 801 ⟩;
avail ← null; mem_end ← mem_top; hi_mem_min ← hi_mem_stat_min;
  { initialize the one-word memory }
var_used ← lo_mem_stat_max + 1 - mem_bot; dyn_used ← hi_mem_stat_usage; { initialize statistics }

```

See also sections 228, 234, 238, 246, 256, 264, 563, 957, 962, 1228, 1314, and 1382.

This code is used in section 8.

**171.** If T<sub>E</sub>X is extended improperly, the *mem* array might get screwed up. For example, some pointers might be wrong, or some “dead” nodes might not have been freed when the last reference to them disappeared. Procedures *check\_mem* and *search\_mem* are available to help diagnose such problems. These procedures make use of two arrays called *free* and *was\_free* that are present only if T<sub>E</sub>X’s debugging routines have been included. (You may want to decrease the size of *mem* while you are debugging.)

```

define free ≡ free_arr
⟨ Global variables 13 ⟩ +=
  { The debug memory arrays have not been allocated yet. }
debug free: packed array [0 .. 9] of boolean; { free cells }
was_free: packed array [0 .. 9] of boolean; { previously free cells }
was_mem_end, was_lo_max, was_hi_min: pointer; { previous mem_end, lo_mem_max, and hi_mem_min }
panicking: boolean; { do we want to check memory constantly? }
gubed

```

```

172.  ⟨ Set initial values of key variables 21 ⟩ +=
debug was_mem_end ← mem_min; { indicate that everything was previously free }
was_lo_max ← mem_min; was_hi_min ← mem_max; panicking ← false;
gubed

```

**173.** Procedure *check\_mem* makes sure that the available space lists of *mem* are well formed, and it optionally prints out all locations that are reserved now but were free the last time this procedure was called.

```

debug procedure check_mem(print_locs : boolean);
label done1, done2; { loop exits }
var p, q: pointer; { current locations of interest in mem }
    clobbered: boolean; { is something amiss? }
begin for p ← mem_min to lo_mem_max do free[p] ← false; { you can probably do this faster }
for p ← hi_mem_min to mem_end do free[p] ← false; { ditto }
< Check single-word avail list 174 >;
< Check variable-size avail list 175 >;
< Check flags of unavailable nodes 176 >;
if print_locs then < Print newly busy locations 177 >;
for p ← mem_min to lo_mem_max do was_free[p] ← free[p];
for p ← hi_mem_min to mem_end do was_free[p] ← free[p]; { was_free ← free might be faster }
    was_mem_end ← mem_end; was_lo_max ← lo_mem_max; was_hi_min ← hi_mem_min;
end;
gubed

```

**174.** < Check single-word *avail* list 174 > ≡  
 p ← avail; q ← null; clobbered ← false;  
**while** p ≠ null **do**  
   **begin if** (p > mem\_end) ∨ (p < hi\_mem\_min) **then** clobbered ← true  
   **else if** free[p] **then** clobbered ← true;  
   **if** clobbered **then**  
     **begin** print\_nl("AVAIL\_list\_clobbered\_at\_"); print\_int(q); **goto** done1;  
     **end;**  
   free[p] ← true; q ← p; p ← link(q);  
   **end;**

          begin print_char("_"); print_int(p);
              end;
        for p ← hi_mem_min to mem_end do
          if ¬free[p] ∧ ((p < was_hi_min) ∨ (p > was_mem_end) ∨ was_free[p]) then
            begin print_char("_"); print_int(p);
                end;
          end
        end
      end

```

This code is used in section 173.

178. The *search\_mem* procedure attempts to answer the question “Who points to node *p*?” In doing so, it fetches *link* and *info* fields of *mem* that might not be of type *two\_halves*. Strictly speaking, this is undefined in Pascal, and it can lead to “false drops” (words that seem to point to *p* purely by coincidence). But for debugging purposes, we want to rule out the places that do *not* point to *p*, so a few false drops are tolerable.

```

debug procedure search_mem(p : pointer); { look for pointers to p }
var q : integer; { current position being searched }
begin for q ← mem_min to lo_mem_max do
  begin if link(q) = p then
    begin print_nl("LINK("); print_int(q); print_char(")");
        end;
    if info(q) = p then
      begin print_nl("INFO("); print_int(q); print_char(")");
          end;
    end;
  end;
for q ← hi_mem_min to mem_end do
  begin if link(q) = p then
    begin print_nl("LINK("); print_int(q); print_char(")");
        end;
    if info(q) = p then
      begin print_nl("INFO("); print_int(q); print_char(")");
          end;
    end;
  end;
⟨ Search eqtb for equivalents equal to p 261 ⟩;
⟨ Search save_stack for equivalents that point to p 291 ⟩;
⟨ Search hypb_list for pointers to p 944 ⟩;
end;
gubed

```

**179. Displaying boxes.** We can reinforce our knowledge of the data structures just introduced by considering two procedures that display a list in symbolic form. The first of these, called *short\_display*, is used in “overfull box” messages to give the top-level description of a list. The other one, called *show\_node\_list*, prints a detailed description of exactly what is in the data structure.

The philosophy of *short\_display* is to ignore the fine points about exactly what is inside boxes, except that ligatures and discretionary breaks are expanded. As a result, *short\_display* is a recursive procedure, but the recursion is never more than one level deep.

A global variable *font\_in\_short\_display* keeps track of the font code that is assumed to be present when *short\_display* begins; deviations from this font will be printed.

```
⟨Global variables 13⟩ +≡
font_in_short_display: integer; { an internal font number }
```

**180.** Boxes, rules, inserts, whatsits, marks, and things in general that are sort of “complicated” are indicated only by printing ‘[]’.

```
procedure short_display(p : integer); { prints highlights of list p }
```

```
  var n: integer; { for replacement counts }
  begin while p > mem_min do
    begin if is_char_node(p) then
      begin if p ≤ mem_end then
        begin if font(p) ≠ font_in_short_display then
          begin if (font(p) > font_max) then print_char("*")
            else ⟨Print the font identifier for font(p) 273⟩;
              print_char("□"); font_in_short_display ← font(p);
            end;
          if font_dir[font(p)] ≠ dir_default then
            begin p ← link(p); print_kanji(info(p));
              end
            else print_ASCII(qo(character(p)));
              end;
            end
          else ⟨Print a short indication of the contents of node p 181⟩;
            p ← link(p);
          end;
        end;
      end;
    end;
```

**181.** ⟨Print a short indication of the contents of node p 181⟩ ≡

```
case type(p) of
  hlist_node, vlist_node, dir_node, ins_node, whatsit_node, mark_node, adjust_node, unset_node: print(" [] ");
  rule_node: print_char("|");
  glue_node: if glue_ptr(p) ≠ zero_glue then print_char("□");
  math_node: print_char("$");
  ligature_node: short_display(lig_ptr(p));
  disc_node: begin short_display(pre_break(p)); short_display(post_break(p));
    n ← replace_count(p);
    while n > 0 do
      begin if link(p) ≠ null then p ← link(p);
        decr(n);
      end;
    end;
  othercases do_nothing
endcases
```

This code is used in section 180.

182. The *show\_node\_list* routine requires some auxiliary subroutines: one to print a font-and-character combination, one to print a token list without its reference count, and one to print a rule dimension.

```

procedure print_font_and_char(p : integer); { prints char_node data }
  begin if p > mem_end then print_esc("CLOBBBERED.")
  else begin if (font(p) > font_max) then print_char("*")
    else ⟨Print the font identifier for font(p) 273;
    print_char("□");
    if font_dir[font(p)] ≠ dir_default then
      begin p ← link(p); print_kanji(info(p));
      end
    else print_ASCII(qo(character(p)));
    end;
  end;

procedure print_mark(p : integer); { prints token list data in braces }
  begin print_char("{");
  if (p < hi_mem_min) ∨ (p > mem_end) then print_esc("CLOBBBERED.")
  else show_token_list(link(p), null, max_print_line - 10);
  print_char("}");
  end;

procedure print_rule_dimen(d : scaled); { prints dimension in rule node }
  begin if is_running(d) then print_char("*")
  else print_scaled(d);
  end;

```

183. Then there is a subroutine that prints glue stretch and shrink, possibly followed by the name of finite units:

```

procedure print_glue(d : scaled; order : integer; s : str_number); { prints a glue component }
  begin print_scaled(d);
  if (order < normal) ∨ (order > filll) then print("foul")
  else if order > normal then
    begin print("fil");
    while order > fil do
      begin print_char("l"); decr(order);
      end;
    end
    else if s ≠ 0 then print(s);
  end;

```

184. The next subroutine prints a whole glue specification.

```

procedure print_spec(p : integer; s : str_number); { prints a glue specification }
  begin if (p < mem_min) ∨ (p ≥ lo_mem_max) then print_char("*")
  else begin print_scaled(width(p));
    if s ≠ 0 then print(s);
    if stretch(p) ≠ 0 then
      begin print("□plus□"); print_glue(stretch(p), stretch_order(p), s);
      end;
    if shrink(p) ≠ 0 then
      begin print("□minus□"); print_glue(shrink(p), shrink_order(p), s);
      end;
    end;
  end;

```

**185.** We also need to declare some procedures that appear later in this documentation.

```

⟨ Declare procedures needed for displaying the elements of mlists 702 ⟩
⟨ Declare the procedure called print_skip_param 231 ⟩

```

**186.** Since boxes can be inside of boxes, *show\_node\_list* is inherently recursive, up to a given maximum number of levels. The history of nesting is indicated by the current string, which will be printed at the beginning of each line; the length of this string, namely *cur\_length*, is the depth of nesting.

Recursive calls on *show\_node\_list* therefore use the following pattern:

```

define node_list_display(#) ≡
    begin append_char("."); show_node_list(#); flush_char;
    end { str_room need not be checked; see show_box below }

```

**187.** A global variable called *depth\_threshold* is used to record the maximum depth of nesting for which *show\_node\_list* will show information. If we have *depth\_threshold* = 0, for example, only the top level information will be given and no sublists will be traversed. Another global variable, called *breadth\_max*, tells the maximum number of items to show at each level; *breadth\_max* had better be positive, or you won't see anything.

```

⟨ Global variables 13 ⟩ +=
depth_threshold: integer; { maximum nesting depth in box displays }
breadth_max: integer; { maximum number of items shown at the same list level }

```

**188.** Now we are ready for *show\_node\_list* itself. This procedure has been written to be “extra robust” in the sense that it should not crash or get into a loop even if the data structures have been messed up by bugs in the rest of the program. You can safely call its parent routine *show\_box*(*p*) for arbitrary values of *p* when you are debugging T<sub>E</sub>X. However, in the presence of bad data, the procedure may fetch a *memory\_word* whose variant is different from the way it was stored; for example, it might try to read *mem*[*p*].*hh* when *mem*[*p*] contains a scaled integer, if *p* is a pointer that has been clobbered or chosen at random.

```

procedure show_node_list(p : integer); { prints a node list symbolically }
    label exit;
    var n: integer; { the number of items already printed at this level }
        g: real; { a glue ratio, as a floating point number }
    begin if cur_length > depth_threshold then
        begin if p > null then print("□□"); { indicate that there's been some truncation }
        return;
        end;
    n ← 0;
    while p > mem_min do
        begin print_ln; print_current_string; { display the nesting history }
        if p > mem_end then { pointer out of range }
            begin print("Bad□link,□display□aborted."); return;
            end;
        incr(n);
        if n > breadth_max then { time to stop }
            begin print("etc."); return;
            end;
        ⟨ Display node p 189 ⟩;
        p ← link(p);
        end;
    exit: end;

```

```

189. < Display node p 189 > ≡
if is_char_node(p) then
  begin print_font_and_char(p);

    end;
  if glue_shrink(p) ≠ 0 then
    begin print(",□shrink□"); print_glue(glue_shrink(p), glue_sign(p), 0);
    end;
  end

```

This code is used in section 190.

192. The code will have to change in this place if *glue\_ratio* is a structured type instead of an ordinary *real*. Note that this routine should avoid arithmetic errors even if the *glue\_set* field holds an arbitrary random value. The following code assumes that a properly formed nonzero *real* number has absolute value  $2^{20}$  or more when it is regarded as an integer; this precaution was adequate to prevent floating point underflow on the author's computer.

```

< Display the value of glue_set(p) 192 > ≡
  g ← float(glue_set(p));
  if (g ≠ float_constant(0)) ∧ (glue_sign(p) ≠ normal) then
    begin print(",□glue□set□");
    if glue_sign(p) = shrinking then print("-□"); { The Unix pc folks removed this restriction with a
      remark that invalid bit patterns were vanishingly improbable, so we follow their example without
      really understanding it. if abs(mem[p + glue_offset].int) < '4000000 then print('?.?') else }

203.  ⟨ Display adjustment p 203 ⟩ ≡
  begin print_esc("vadjust"); node_list_display(adjust_ptr(p)); { recursive call }
  end

```

This code is used in section 189.

**204.** The recursive machinery is started by calling *show\_box*.

```

procedure show_box(p : pointer);
  begin ⟨ Assign the values depth_threshold ← show_box_depth and breadth_max ← show_box_breadth 242 ⟩;
  if breadth_max ≤ 0 then breadth_max ← 5;
  if pool_ptr + depth_threshold ≥ pool_size then depth_threshold ← pool_size - pool_ptr - 1;
    { now there's enough room for prefix string }
  show_node_list(p); { the show starts at p }
  print_ln;
  end;

```

**205. Destroying boxes.** When we are done with a node list, we are obliged to return it to free storage, including all of its sublists. The recursive procedure *flush\_node\_list* does this for us.

**206.** First, however, we shall consider two non-recursive procedures that do simpler tasks. The first of these, *delete\_token\_ref*, is called when a pointer to a token list's reference count is being removed. This means that the token list should disappear if the reference count was *null*, otherwise the count should be decreased by one.

```

define token_ref_count(#) ≡ info(#) { reference count preceding a token list }
procedure delete_token_ref(p : pointer);
    { p points to the reference count of a token list that is losing one reference }
begin if token_ref_count(p) = null then flush_list(p)
else decr(token_ref_count(p));
end;

```

**207.** Similarly, *delete\_glue\_ref* is called when a pointer to a glue specification is being withdrawn.

```

define fast_delete_glue_ref(#) ≡
    begin if glue_ref_count(#) = null then free_node(#, glue_spec_size)
    else decr(glue_ref_count(#));
    end
procedure delete_glue_ref(p : pointer); { p points to a glue specification }
    fast_delete_glue_ref(p);

```

**208.** Now we are ready to delete any node list, recursively. In practice, the nodes deleted are usually charnodes (about 2/3 of the time), and they are glue nodes in about half of the remaining cases.

```

procedure flush_node_list(p : pointer); { erase list of nodes starting at p }
  label done; { go here when node p has been freed }
  var q: pointer; { successor to node p }
  begin while p ≠ null do
    begin q ← link(p);
    if is_char_node(p) then free_avail(p)
    else begin case type(p) of
      hlist_node, vlist_node, dir_node, unset_node: begin flush_node_list(list_ptr(p));
        fast_delete_glue_ref(space_ptr(p)); fast_delete_glue_ref(xspace_ptr(p)); free_node(p, box_node_size);
        goto done;
      end;
      rule_node: begin free_node(p, rule_node_size); goto done;
      end;
      ins_node: begin flush_node_list(ins_ptr(p)); delete_glue_ref(split_top_ptr(p));
        free_node(p, ins_node_size); goto done;
      end;
      whatsit_node: ⟨ Wipe out the whatsit node p and goto done 1371 ⟩;
      glue_node: begin fast_delete_glue_ref(glue_ptr(p));
        if leader_ptr(p) ≠ null then flush_node_list(leader_ptr(p));
        end;
      disp_node, kern_node, math_node, penalty_node: do_nothing;
      ligature_node: flush_node_list(lig_ptr(p));
      mark_node: delete_token_ref(mark_ptr(p));
      disc_node: begin flush_node_list(pre_break(p)); flush_node_list(post_break(p));
        end;
      adjust_node: flush_node_list(adjust_ptr(p));
      ⟨ Cases of flush_node_list that arise in mlists only 709 ⟩
      othercases confusion("flushing")
    endcases;
    free_node(p, small_node_size);
  done: end;
  p ← q;
end;
end;

```

**209. Copying boxes.** Another recursive operation that acts on boxes is sometimes needed: The procedure *copy\_node\_list* returns a pointer to another node list that has the same structure and meaning as the original. Note that since glue specifications and token lists have reference counts, we need not make copies of them. Reference counts can never get too large to fit in a halfword, since each pointer to a node is in a different memory address, and the total number of memory addresses fits in a halfword.

(Well, there actually are also references from outside *mem*; if the *save\_stack* is made arbitrarily large, it would theoretically be possible to break T<sub>E</sub>X by overflowing a reference count. But who would want to do that?)

```
define add_token_ref(#) ≡ incr(token_ref_count(#)) { new reference to a token list }
define add_glue_ref(#) ≡ incr(glue_ref_count(#)) { new reference to a glue spec }
```

**210.** The copying procedure copies words en masse without bothering to look at their individual fields. If the node format changes—for example, if the size is altered, or if some link field is moved to another relative position—then this code may need to be changed too.

```
function copy_node_list(p : pointer): pointer;
    { makes a duplicate of the node list that starts at p and returns a pointer to the new list }
var h: pointer; { temporary head of copied list }
    q: pointer; { previous position in new list }
    r: pointer; { current node being fabricated for new list }
    words: 0 .. 5; { number of words remaining to be copied }
begin h ← get_avail; q ← h;
while p ≠ null do
    begin ⟨ Make a copy of node p in node r 211 ⟩;
    link(q) ← r; q ← r; p ← link(p);
    end;
    link(q) ← null; q ← link(h); free_avail(h); copy_node_list ← q;
end;
```

```
211. ⟨ Make a copy of node p in node r 211 ⟩ ≡
    words ← 1; { this setting occurs in more branches than any other }
    if is_char_node(p) then r ← get_avail
    else ⟨ Case statement to copy different types and set words to the number of initial words not yet
        copied 212 ⟩;
    while words > 0 do
        begin decr(words); mem[r + words] ← mem[p + words];
        end
```

This code is used in section 210.

```

212. ⟨Case statement to copy different types and set words to the number of initial words not yet
copied 212⟩ ≡
case type(p) of
  dir_node, hlist_node, vlist_node, unset_node: begin r ← get_node(box_node_size);
    mem[r + 7] ← mem[p + 7]; mem[r + 6] ← mem[p + 6]; mem[r + 5] ← mem[p + 5];
    { copy the last three words }
    add_glue_ref(space_ptr(r)); add_glue_ref(xspace_ptr(r)); list_ptr(r) ← copy_node_list(list_ptr(p));
    { this affects mem[r + 5] }
    words ← 5;
  end;
  rule_node: begin r ← get_node(rule_node_size); words ← rule_node_size;
  end;
  ins_node: begin r ← get_node(ins_node_size); mem[r + 5] ← mem[p + 5]; mem[r + 4] ← mem[p + 4];
    add_glue_ref(split_top_ptr(p)); ins_ptr(r) ← copy_node_list(ins_ptr(p)); { this affects mem[r + 4] }
    words ← ins_node_size - 2;
  end;
  whatsit_node: ⟨Make a partial copy of the whatsit node p and make r point to it; set words to the
    number of initial words not yet copied 1370⟩;
  glue_node: begin r ← get_node(small_node_size); add_glue_ref(glue_ptr(p)); glue_ptr(r) ← glue_ptr(p);
    leader_ptr(r) ← copy_node_list(leader_ptr(p));
  end;
  disp_node, kern_node, math_node, penalty_node: begin r ← get_node(small_node_size);
    words ← small_node_size;
  end;
  ligature_node: begin r ← get_node(small_node_size); mem[lig_char(r)] ← mem[lig_char(p)];
    { copy font and character }
    lig_ptr(r) ← copy_node_list(lig_ptr(p));
  end;
  disc_node: begin r ← get_node(small_node_size); pre_break(r) ← copy_node_list(pre_break(p));
    post_break(r) ← copy_node_list(post_break(p));
  end;
  mark_node: begin r ← get_node(small_node_size); add_token_ref(mark_ptr(p));
    words ← small_node_size;
  end;
  adjust_node: begin r ← get_node(small_node_size); adjust_ptr(r) ← copy_node_list(adjust_ptr(p));
  end; { words = 1 = small_node_size - 1 }
othercases confusion("copying")
endcases

```

This code is used in section 211.

**213. The command codes.** Before we can go any further, we need to define symbolic names for the internal code numbers that represent the various commands obeyed by T<sub>E</sub>X. These codes are somewhat arbitrary, but not completely so. For example, the command codes for character types are fixed by the language, since a user says, e.g., ‘`\catcode \ $ = 3`’ to make \$ a math delimiter, and the command code *math\_shift* is equal to 3. Some other codes have been made adjacent so that **case** statements in the program need not consider cases that are widely spaced, or so that **case** statements can be replaced by **if** statements.

At any rate, here is the list, for future reference. First come the “catcode” commands, several of which share their numeric codes with ordinary commands when the catcode cannot emerge from T<sub>E</sub>X’s scanning routine.

```

define escape = 0 {escape delimiter (called \ in The TEXbook)}
define relax = 0 {do nothing ( \relax )}
define left_brace = 1 {beginning of a group ( { )}
define right_brace = 2 {ending of a group ( } )}
define math_shift = 3 {mathematics shift character ( $ )}
define tab_mark = 4 {alignment delimiter ( &, \span )}
define car_ret = 5 {end of line ( carriage_return, \cr, \crcr )}
define out_param = 5 {output a macro parameter}
define mac_param = 6 {macro parameter symbol ( # )}
define sup_mark = 7 {superscript ( ^ )}
define sub_mark = 8 {subscript ( _ )}
define ignore = 9 {characters to ignore ( ^^@ )}
define endv = 9 {end of <vj> list in alignment template}
define spacer = 10 {characters equivalent to blank space ( _ )}
define letter = 11 {characters regarded as letters ( A..Z, a..z )}
define other_char = 12 {none of the special character types}
define active_char = 13 {characters that invoke macros ( ~ )}
define par_end = 13 {end of paragraph ( \par )}
define match = 13 {match a macro parameter}
define comment = 14 {characters that introduce comments ( % )}
define end_match = 14 {end of parameters to macro}
define stop = 14 {end of job ( \end, \dump )}
define invalid_char = 15 {characters that shouldn't appear ( ^^? )}
define delim_num = 15 {specify delimiter numerically ( \delimiter )}
define kanji = 16 {kanji}
define kana = 17 {hiragana, katakana, alphabet}
define other_kchar = 18 {kanji codes}
define max_char_code = 18 {largest catcode for individual characters}

```

214. Next are the ordinary run-of-the-mill command codes. Codes that are *min\_internal* or more represent internal quantities that might be expanded by ‘\the’.

```

define char_num = max_char_code + 1 {character specified numerically ( \char )}

define box_ref = max_command + 19 { the equivalent points to a box node, or is null }
define data = max_command + 20 { the equivalent is simply a halfword number }

```

**217. The semantic nest.** T<sub>E</sub>X is typically in the midst of building many lists at once. For example, when a math formula is being processed, T<sub>E</sub>X is in math mode and working on an mlist; this formula has temporarily interrupted T<sub>E</sub>X from being in horizontal mode and building the hlist of a paragraph; and this paragraph has temporarily interrupted T<sub>E</sub>X from being in vertical mode and building the vlist for the next page of a document. Similarly, when a `\vbox` occurs inside of an `\hbox`, T<sub>E</sub>X is temporarily interrupted from working in restricted horizontal mode, and it enters internal vertical mode. The “semantic nest” is a stack that keeps track of what lists and modes are currently suspended.

At each level of processing we are in one of six modes:

*vmode* stands for vertical mode (the page builder);  
*hmode* stands for horizontal mode (the paragraph builder);  
*mmode* stands for displayed formula mode;  
 –*vmode* stands for internal vertical mode (e.g., in a `\vbox`);  
 –*hmode* stands for restricted horizontal mode (e.g., in an `\hbox`);  
 –*mmode* stands for math formula mode (not displayed).

The mode is temporarily set to zero while processing `\write` texts in the *ship\_out* routine.

Numeric values are assigned to *vmode*, *hmode*, and *mmode* so that T<sub>E</sub>X’s “big semantic switch” can select the appropriate thing to do by computing the value  $abs(mode) + cur\_cmd$ , where *mode* is the current mode and *cur\_cmd* is the current command code.

```

define vmode = 1 { vertical mode }
define hmode = vmode + max_command + 1 { horizontal mode }
define mmode = hmode + max_command + 1 { math mode }
procedure print_mode(m : integer); { prints the mode represented by m }
begin if m > 0 then
  case m div (max_command + 1) of
    0: print("vertical_mode");
    1: print("horizontal_mode");
    2: print("display_math_mode");
  end
else if m = 0 then print("no_mode")
  else case (-m) div (max_command + 1) of
    0: print("internal_vertical_mode");
    1: print("restricted_horizontal_mode");
    2: print("math_mode");
  end;
end;
procedure print_in_mode(m : integer); { prints the mode represented by m }
begin if m > 0 then
  case m div (max_command + 1) of
    0: print("_in_vertical_mode");
    1: print("_in_horizontal_mode");
    2: print("_in_display_math_mode");
  end
else if m = 0 then print("_in_no_mode")
  else case (-m) div (max_command + 1) of
    0: print("_in_internal_vertical_mode");
    1: print("_in_restricted_horizontal_mode");
    2: print("_in_math_mode");
  end;
end;

```

**218.** The state of affairs at any semantic level can be represented by five values:

*mode* is the number representing the semantic mode, as just explained.

*head* is a *pointer* to a list head for the list being built; *link(head)* therefore points to the first element of the list, or to *null* if the list is empty.

*tail* is a *pointer* to the final node of the list being built; thus, *tail = head* if and only if the list is empty.

*prev\_graf* is the number of lines of the current paragraph that have already been put into the present vertical list.

*aux* is an auxiliary *memory\_word* that gives further information that is needed to characterize the situation.

In vertical mode, *aux* is also known as *prev\_depth*; it is the scaled value representing the depth of the previous box, for use in baseline calculations, or it is  $\leq -1000\text{pt}$  if the next box on the vertical list is to be exempt from baseline calculations. In horizontal mode, *aux* is also known as *space\_factor* and *clang*; it holds the current space factor used in spacing calculations, and the current language used for hyphenation. (The value of *clang* is undefined in restricted horizontal mode.) In math mode, *aux* is also known as *incomplete\_noad*; if not *null*, it points to a record that represents the numerator of a generalized fraction for which the denominator is currently being formed in the current list.

There is also a sixth quantity, *mode\_line*, which correlates the semantic nest with the user's input; *mode\_line* contains the source line number at which the current level of nesting was entered. The negative of this line number is the *mode\_line* at the level of the user's output routine.

In horizontal mode, the *prev\_graf* field is used for initial language data.

The semantic nest is an array called *nest* that holds the *mode*, *head*, *tail*, *prev\_graf*, *aux*, and *mode\_line* values for all semantic levels below the currently active one. Information about the currently active level is kept in the global quantities *mode*, *head*, *tail*, *prev\_graf*, *aux*, and *mode\_line*, which live in a Pascal record that is ready to be pushed onto *nest* if necessary.

**define** *ignore\_depth*  $\equiv -65536000$  { *prev\_depth* value that is ignored }

(Types in the outer block 18)  $\equiv$

```
list_state_record = record mode_field: -mmode .. mmode; dir_field, adj_dir_field: -dir_yoko .. dir_yoko;
  pdisp_field: scaled;
  head_field, tail_field, pnode_field, last_jchr_field: pointer;
  pg_field, ml_field: integer; aux_field: memory_word;
end;
```

```

219. define mode ≡ cur_list.mode_field { current mode }
define direction ≡ cur_list.dir_field { current direction }
define adjust_dir ≡ cur_list.adj_dir_field { current adjust direction }
define head ≡ cur_list.head_field { header node of current list }
define tail ≡ cur_list.tail_field { final node on current list }
define prev_node ≡ cur_list.pnode_field { previous to last disp_node }
define prev_disp ≡ cur_list.pdisp_field { displacemant at prev_node }
define last_jchr ≡ cur_list.last_jchr_field { final jchar node on current list }
define prev_graf ≡ cur_list.pg_field { number of paragraph lines accumulated }
define aux ≡ cur_list.aux_field { auxiliary data about the current list }
define prev_depth ≡ aux.sc { the name of aux in vertical mode }
define space_factor ≡ aux.hh.lh { part of aux in horizontal mode }
define clang ≡ aux.hh.rh { the other part of aux in horizontal mode }
define incompleat_noad ≡ aux.int { the name of aux in math mode }
define mode_line ≡ cur_list.ml_field { source file line number at beginning of list }

```

⟨Global variables 13⟩ +=

```

nest: ↑list_state_record;
nest_ptr: 0 .. nest_size; { first unused location of nest }
max_nest_stack: 0 .. nest_size; { maximum of nest_ptr when pushing }
cur_list: list_state_record; { the “top” semantic state }
shown_mode: -mmode .. mmode; { most recent mode shown by \tracingcommands }

```

**220.** Here is a common way to make the current list grow:

```

define tail_append(#) ≡
  begin link(tail) ← #; tail ← link(tail);
  end
define prev_append(#) ≡
  begin link(prev_node) ← #; link(link(prev_node)) ← tail; prev_node ← link(prev_node);
  end

```

**221.** We will see later that the vertical list at the bottom semantic level is split into two parts; the “current page” runs from *page\_head* to *page\_tail*, and the “contribution list” runs from *contrib\_head* to *tail* of semantic level zero. The idea is that contributions are first formed in vertical mode, then “contributed” to the current page (during which time the page-breaking decisions are made). For now, we don’t need to know any more details about the page-building process.

⟨Set initial values of key variables 21⟩ +=

```

nest_ptr ← 0; max_nest_stack ← 0; mode ← vmode; head ← contrib_head; tail ← contrib_head;
prev_node ← tail; direction ← dir_yoko; adjust_dir ← direction; prev_disp ← 0; last_jchr ← null;
prev_depth ← ignore_depth; mode_line ← 0; prev_graf ← 0; shown_mode ← 0;
  { The following piece of code is a copy of module 991: }
page_contents ← empty; page_tail ← page_head; { link(page_head) ← null; }
last_glue ← max_halfword; last_penalty ← 0; last_kern ← 0; page_depth ← 0; page_max_depth ← 0;

```

**222.** When T<sub>E</sub>X's work on one level is interrupted, the state is saved by calling *push\_nest*. This routine changes *head* and *tail* so that a new (empty) list is begun; it does not change *mode* or *aux*.

```

procedure push_nest; { enter a new semantic level, save the old }
  begin if nest_ptr > max_nest_stack then
    begin max_nest_stack ← nest_ptr;
    if nest_ptr = nest_size then overflow("semantic_nest_size", nest_size);
    end;
  nest[nest_ptr] ← cur_list; { stack the record }
  incr(nest_ptr); head ← new_null_box; tail ← head; prev_node ← tail; prev_graf ← 0; prev_disp ← 0;
  last_jchr ← null; mode_line ← line;
end;

```

**223.** Conversely, when T<sub>E</sub>X is finished on the current level, the former state is restored by calling *pop\_nest*. This routine will never be called at the lowest semantic level, nor will it be called unless *head* is a node that should be returned to free memory.

```

procedure pop_nest; { leave a semantic level, re-enter the old }
  begin fast_delete_glue_ref(space_ptr(head)); fast_delete_glue_ref(xspace_ptr(head));
  free_node(head, box_node_size); decr(nest_ptr); cur_list ← nest[nest_ptr];
end;

```

**224.** Here is a procedure that displays what T<sub>E</sub>X is working on, at all levels.

```

procedure print_totals; forward;
procedure show_activities;
  var p: 0 .. nest_size; { index into nest }
  m: -mmode .. mmode; { mode }
  a: memory_word; { auxiliary }
  q, r: pointer; { for showing the current page }
  t: integer; { ditto }
  begin nest[nest_ptr] ← cur_list; { put the top level into the array }
  print_nl(""); print_ln;
  for p ← nest_ptr downto 0 do
    begin m ← nest[p].mode_field; a ← nest[p].aux_field; print_nl("###");
    print_direction(nest[p].dir_field); print(" ,"); print_mode(m); print("_entered_at_line");
    print_int(abs(nest[p].ml_field));
    if m = hmode then
      if nest[p].pg_field ≠ '4060000 then
        begin print("_(language"); print_int(nest[p].pg_field mod '200000); print(":hyphenmin");
        print_int(nest[p].pg_field div '2000000); print_char(" ,");
        print_int((nest[p].pg_field div '200000) mod '100); print_char(")");
        end;
      if nest[p].ml_field < 0 then print("_(\output_routine)");
    if p = 0 then
      begin ⟨ Show the status of the current page 997 ⟩;
      if link(contrib_head) ≠ null then print_nl("###_recent_contributions:");
      end;
    show_box(link(nest[p].head_field)); ⟨ Show the auxiliary field, a 225 ⟩;
  end;
end;

```

225.  $\langle$  Show the auxiliary field,  $a$  225  $\rangle \equiv$

```

case abs(m) div (max_command + 1) of
0: begin print_nl("prevdepth_");
  if a.sc ≤ ignore_depth then print("ignored")
  else print_scaled(a.sc);
  if nest[p].pg_field ≠ 0 then
    begin print("_prevgraf_"); print_int(nest[p].pg_field);
    if nest[p].pg_field ≠ 1 then print("_lines")
    else print("_line");
    end;
  end;
1: begin print_nl("spacefactor_"); print_int(a.hh.lh);
  if m > 0 then if a.hh.rh > 0 then
    begin print("_current_language_"); print_int(a.hh.rh); end;
  end;
2: if a.int ≠ null then
  begin print("this_will_be_denominator_of:"); show_box(a.int); end;
end { there are no other cases }

```

This code is used in section 224.

**226. The table of equivalents.** Now that we have studied the data structures for T<sub>E</sub>X’s semantic routines, we ought to consider the data structures used by its syntactic routines. In other words, our next concern will be the tables that T<sub>E</sub>X looks at when it is scanning what the user has written.

The biggest and most important such table is called *eqtb*. It holds the current “equivalents” of things; i.e., it explains what things mean or what their current values are, for all quantities that are subject to the nesting structure provided by T<sub>E</sub>X’s grouping mechanism. There are six parts to *eqtb*:

- 1) *eqtb*[*active\_base* .. (*hash\_base* – 1)] holds the current equivalents of single-character control sequences.
- 2) *eqtb*[*hash\_base* .. (*glue\_base* – 1)] holds the current equivalents of multiletter control sequences.
- 3) *eqtb*[*glue\_base* .. (*local\_base* – 1)] holds the current equivalents of glue parameters like the current *baselineskip*.
- 4) *eqtb*[*local\_base* .. (*int\_base* – 1)] holds the current equivalents of local halfword quantities like the current box registers, the current “catcodes,” the current font, and a pointer to the current paragraph shape. Additionally region 4 contains the table with MLT<sub>E</sub>X’s character substitution definitions.
- 5) *eqtb*[*int\_base* .. (*dimen\_base* – 1)] holds the current equivalents of fullword integer parameters like the current hyphenation penalty.
- 6) *eqtb*[*dimen\_base* .. *eqtb\_size*] holds the current equivalents of fullword dimension parameters like the current *hsize* or amount of hanging indentation.

Note that, for example, the current amount of *baselineskip* glue is determined by the setting of a particular location in region 3 of *eqtb*, while the current meaning of the control sequence ‘\baselineskip’ (which might have been changed by \def or \let) appears in region 2.

**227.** Each entry in *eqtb* is a *memory\_word*. Most of these words are of type *two\_halves*, and subdivided into three fields:

- 1) The *eq\_level* (a quarterword) is the level of grouping at which this equivalent was defined. If the level is *level\_zero*, the equivalent has never been defined; *level\_one* refers to the outer level (outside of all groups), and this level is also used for global definitions that never go away. Higher levels are for equivalents that will disappear at the end of their group.
- 2) The *eq\_type* (another quarterword) specifies what kind of entry this is. There are many types, since each T<sub>E</sub>X primitive like \hbox, \def, etc., has its own special code. The list of command codes above includes all possible settings of the *eq\_type* field.
- 3) The *equiv* (a halfword) is the current equivalent value. This may be a font number, a pointer into *mem*, or a variety of other things.

```

define eq_level_field(#) ≡ #.hh.b1
define eq_type_field(#) ≡ #.hh.b0
define equiv_field(#) ≡ #.hh.rh
define eq_level(#) ≡ eq_level_field(eqtb[#]) { level of definition }
define eq_type(#) ≡ eq_type_field(eqtb[#]) { command code for equivalent }
define equiv(#) ≡ equiv_field(eqtb[#]) { equivalent value }
define level_zero = min_quarterword { level for undefined quantities }
define level_one = level_zero + 1 { outermost level for defined quantities }

```

**228.** Many locations in *eqtb* have symbolic names. The purpose of the next paragraphs is to define these names, and to set up the initial values of the equivalents.

In the first region we have 256 equivalents for “active characters” that act as control sequences, followed by 256 equivalents for single-character control sequences.

Then comes region 2, which corresponds to the hash table that we will define later. The maximum address in this region is used for a dummy control sequence that is perpetually undefined. There also are several locations for control sequences that are perpetually defined (since they are used in error recovery).

```

define active_base = 1 {beginning of region 1, for active character equivalents }
define single_base = active_base + 256 {equivalents of one-character control sequences }
define null_cs = single_base + 256 {equivalent of \csname\endcsname }
define hash_base = null_cs + 1 {beginning of region 2, for the hash table }
define frozen_control_sequence = hash_base + hash_size {for error recovery }
define frozen_protection = frozen_control_sequence {inaccessible but definable }
define frozen_cr = frozen_control_sequence + 1 {permanent '\cr'}
define frozen_end_group = frozen_control_sequence + 2 {permanent '\endgroup'}
define frozen_right = frozen_control_sequence + 3 {permanent '\right'}
define frozen_fi = frozen_control_sequence + 4 {permanent '\fi'}
define frozen_end_template = frozen_control_sequence + 5 {permanent '\endtemplate'}
define frozen_endv = frozen_control_sequence + 6 {second permanent '\endtemplate'}
define frozen_relax = frozen_control_sequence + 7 {permanent '\relax'}
define end_write = frozen_control_sequence + 8 {permanent '\endwrite'}
define frozen_dont_expand = frozen_control_sequence + 9 {permanent '\notexpanded:'}
define frozen_special = frozen_control_sequence + 10 {permanent '\special'}
define frozen_null_font = frozen_control_sequence + 11 {permanent '\nullfont'}
define font_id_base = frozen_null_font - font_base {begins table of 257 permanent font identifiers }
define undefined_control_sequence = frozen_null_font + max_font_max + 1 {dummy location }
define glue_base = undefined_control_sequence + 1 {beginning of region 3 }

```

(Initialize table entries (done by INITEX only) 170) +≡

```

eq_type(undefined_control_sequence) ← undefined_cs; equiv(undefined_control_sequence) ← null;
eq_level(undefined_control_sequence) ← level_zero;
for k ← active_base to eqtb_top do eqtb[k] ← eqtb[undefined_control_sequence];

```

**229.** Here is a routine that displays the current meaning of an *eqtb* entry in region 1 or 2. (Similar routines for the other regions will appear below.)

(Show equivalent *n*, in region 1 or 2 229) ≡

```

begin sprint_cs(n); print_char("="); print_cmd_chr(eq_type(n), equiv(n));
if eq_type(n) ≥ call then
  begin print_char(":"); show_token_list(link(equiv(n)), null, 32);
  end;
end

```

This code is used in section 258.

**230.** Region 3 of *eqtb* contains the 256 `\skip` registers, as well as the glue parameters defined here. It is important that the “muskip” parameters have larger numbers than the others.

```

define line_skip_code = 0 { interline glue if baseline_skip is infeasible }
define baseline_skip_code = 1 { desired glue between baselines }

define kanji_skip ≡ glue_par(kanji_skip_code)
define xkanji_skip ≡ glue_par(xkanji_skip_code)

```

⟨ Current *mem* equivalent of glue parameter number *n* 230 ⟩ ≡ *glue\_par*(*n*)

This code is used in sections 158 and 160.

**231.** Sometimes we need to convert T<sub>E</sub>X's internal code numbers into symbolic form. The *print\_skip\_param* routine gives the symbolic name of a glue parameter.

```

⟨Declare the procedure called print_skip_param 231⟩ ≡
procedure print_skip_param(n : integer);
  begin case n of
    line_skip_code: print_esc("lineskip");
    baseline_skip_code: print_esc("baselineskip");
    par_skip_code: print_esc("parskip");
    above_display_skip_code: print_esc("abovedisplayskip");
    below_display_skip_code: print_esc("belowdisplayskip");
    above_display_short_skip_code: print_esc("abovedisplayshortskip");
    below_display_short_skip_code: print_esc("belowdisplayshortskip");
    left_skip_code: print_esc("leftskip");
    right_skip_code: print_esc("rightskip");
    top_skip_code: print_esc("topskip");
    split_top_skip_code: print_esc("splittopskip");
    tab_skip_code: print_esc("tabskip");
    space_skip_code: print_esc("spaceskip");
    xspace_skip_code: print_esc("xspaceskip");
    par_fill_skip_code: print_esc("parfillskip");
    thin_mu_skip_code: print_esc("thinmuskip");
    med_mu_skip_code: print_esc("medmuskip");
    thick_mu_skip_code: print_esc("thickmuskip");
    kanji_skip_code: print_esc("kanjiskip");
    xkanji_skip_code: print_esc("xkanjiskip");
    jfm_skip: print("refer_from_jfm");
    othercases print(" [unknown_glue_parameter!]")
  endcases;
end;

```

This code is used in section 185.

**232.** The symbolic names for glue parameters are put into T<sub>E</sub>X's hash table by using the routine called *primitive*, defined below. Let us enter them now, so that we don't have to list all those parameter names anywhere else.

```

⟨Put each of TEX's primitives into the hash table 232⟩ ≡
  primitive("lineskip", assign_glue, glue_base + line_skip_code);
  primitive("baselineskip", assign_glue, glue_base + baseline_skip_code);
  primitive("parskip", assign_glue, glue_base + par_skip_code);
  primitive("abovedisplayskip", assign_glue, glue_base + above_display_skip_code);
  primitive("belowdisplayskip", assign_glue, glue_base + below_display_skip_code);
  primitive("abovedisplaysshortskip", assign_glue, glue_base + above_display_short_skip_code);
  primitive("belowdisplaysshortskip", assign_glue, glue_base + below_display_short_skip_code);
  primitive("leftskip", assign_glue, glue_base + left_skip_code);
  primitive("rightskip", assign_glue, glue_base + right_skip_code);
  primitive("topskip", assign_glue, glue_base + top_skip_code);
  primitive("splittopskip", assign_glue, glue_base + split_top_skip_code);
  primitive("tabskip", assign_glue, glue_base + tab_skip_code);
  primitive("spaceskip", assign_glue, glue_base + space_skip_code);
  primitive("xspaceskip", assign_glue, glue_base + xspace_skip_code);
  primitive("parfillskip", assign_glue, glue_base + par_fill_skip_code);
  primitive("thinmuskip", assign_mu_glue, glue_base + thin_mu_skip_code);
  primitive("medmuskip", assign_mu_glue, glue_base + med_mu_skip_code);
  primitive("thickmuskip", assign_mu_glue, glue_base + thick_mu_skip_code);
  primitive("kanjiskip", assign_glue, glue_base + kanji_skip_code);
  primitive("xkanjiskip", assign_glue, glue_base + xkanji_skip_code);

```

**238.** We initialize most things to null or undefined values. An undefined font is represented by the internal code *font\_base*.

However, the character code tables are given initial values based on the conventional interpretation of ASCII code. These initial values should not be changed when T<sub>E</sub>X is adapted for use with non-English languages; all changes to the initialization conventions should be made in format packages, not in T<sub>E</sub>X itself, so that global interchange of formats is possible.

```

**242.** Region 5 of *eqtb* contains the integer parameters and registers defined here, as well as the *del\_code* table. The latter table differs from the *cat\_code* .. *math\_code* tables that precede it, since delimiter codes are fullword integers while the other kinds of codes occupy at most a halfword. This is what makes region 5 different from region 4. We will store the *eq\_level* information in an auxiliary array of quarterwords that will be defined later.

245. ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +≡  
*assign\_int*: if *chr\_code* < *count\_base* then *print\_param*(*chr\_code* − *int\_base*)  
 else begin *print\_esc*("count"); *print\_int*(*chr\_code* − *count\_base*);  
 end;

246. The integer parameters should really be initialized by a macro package; the following initialization does the minimum to keep T<sub>E</sub>X from complete failure.

```

⟨Initialize table entries (done by INITEX only) 170⟩ +≡
for k ← int_base to del_code_base − 1 do eqtb[k].int ← 0;
char_sub_def_min ← 256; char_sub_def_max ← −1; { allow \charsubdef for char 0 }
{ tracing_char_sub_def ← 0 is already done }
mag ← 1000; tolerance ← 10000; hang_after ← 1; max_dead_cycles ← 25; escape_char ← "\";
end_line_char ← carriage_return;
for k ← 0 to 255 do del_code(k) ← −1;
del_code(".") ← 0; { this null delimiter is used in error recovery }

```

247. The following procedure, which is called just before T<sub>E</sub>X initializes its input and output, establishes the initial values of the date and time. It calls a macro-defined *date\_and\_time* routine. *date\_and\_time* in turn is a C macro, which calls *get\_date\_and\_time*, passing it the addresses of the day, month, etc., so they can be set by the routine. *get\_date\_and\_time* also sets up interrupt catching if that is conditionally compiled in the C code.

```

define fix_date_and_time ≡ date_and_time(time, day, month, year)

```

248. ⟨Show equivalent *n*, in region 5 248⟩ ≡  
 begin if *n* < *count\_base* then *print\_param*(*n* − *int\_base*)  
 else if *n* < *del\_code\_base* then  
 begin *print\_esc*("count"); *print\_int*(*n* − *count\_base*);  
 end  
 else begin *print\_esc*("delcode"); *print\_int*(*n* − *del\_code\_base*);  
 end;  
*print\_char*("="); *print\_int*(eqtb[*n*].int);  
 end

This code is used in section 258.

249. ⟨Set variable *c* to the current escape character 249⟩ ≡  
*c* ← *escape\_char*

This code is used in section 64.

**250.**  $\langle$  Character  $s$  is the current new-line character 250  $\rangle \equiv$   
 $s = \text{new\_line\_char}$

This code is used in sections 59 and 60.

**251.** T<sub>E</sub>X is occasionally supposed to print diagnostic information that goes only into the transcript file, unless *tracing\_online* is positive. Here are two routines that adjust the destination of print commands:

**procedure** *begin\_diagnostic*; { prepare to do some tracing }

**begin** *old\_setting*  $\leftarrow$  *selector*;

**if** (*tracing\_online*  $\leq$  0)  $\wedge$  (*selector* = *term\_and\_log*) **then**

**begin** *decr*(*selector*);

**if** *history* = *spotless* **then** *history*  $\leftarrow$  *warning\_issued*;

**end**;

**end**;

**procedure** *end\_diagnostic*(*blank\_line* : *boolean*); { restore proper conditions after tracing }

**begin** *print\_nl*("");

**if** *blank\_line* **then** *print\_ln*;

*selector*  $\leftarrow$  *old\_setting*;

**end**;

**252.** Of course we had better declare another global variable, if the previous routines are going to work.

$\langle$  Global variables 13  $\rangle + \equiv$

*old\_setting*: 0 .. *max\_selector*;

**253.** The final region of *eqtb* contains the dimension parameters defined here, and the 256 `\dimen` registers.

        else if n < kinsoku_penalty_base then ⟨ Show equivalent n, in region 6 257 ⟩
          else if n ≤ eqtb_size then print("kinsoku")
            else print_char("?"); { this can't happen either }
        end;
      end;
    end;
  end;
tats

```

**259.** The last two regions of *eqtb* have fullword values instead of the three fields *eq\_level*, *eq\_type*, and *equiv*. An *eq\_type* is unnecessary, but T<sub>E</sub>X needs to store the *eq\_level* information in another array called *xreq\_level*.

```

⟨ Global variables 13 ⟩ +≡
zqtb: ↑memory_word;
xreq_level: array [int_base .. eqtb_size] of quarterword;

```

```

260. ⟨ Set initial values of key variables 21 ⟩ +≡
for k ← int_base to eqtb_size do xreq_level[k] ← level_one;

```

**261.** When the debugging routine *search\_mem* is looking for pointers having a given value, it is interested only in regions 1 to 3 of *eqtb*, and in the first part of region 4.

```

⟨ Search eqtb for equivalents equal to p 261 ⟩ ≡
for q ← active_base to box_base + 255 do
  begin if equiv(q) = p then
    begin print_nl("EQUIV("); print_int(q); print_char(")");
    end;
  end

```

This code is used in section 178.

**262. The hash table.** Control sequences are stored and retrieved by means of a fairly standard hash table algorithm called the method of “coalescing lists” (cf. Algorithm 6.4C in *The Art of Computer Programming*). Once a control sequence enters the table, it is never removed, because there are complicated situations involving `\gdef` where the removal of a control sequence at the end of a group would be a mistake preventable only by the introduction of a complicated reference-count mechanism.

The actual sequence of letters forming a control sequence identifier is stored in the *str\_pool* array together with all the other strings. An auxiliary array *hash* consists of items with two halfword fields per word. The first of these, called *next(p)*, points to the next identifier belonging to the same coalesced list as the identifier corresponding to *p*; and the other, called *text(p)*, points to the *str\_start* entry for *p*’s identifier. If position *p* of the hash table is empty, we have *text(p)* = 0; if position *p* is either empty or the end of a coalesced hash list, we have *next(p)* = 0. An auxiliary pointer variable called *hash\_used* is maintained in such a way that all locations  $p \geq \textit{hash\_used}$  are nonempty. The global variable *cs\_count* tells how many multiletter control sequences have been defined, if statistics are being kept.

A global boolean variable called *no\_new\_control\_sequence* is set to *true* during the time that new hash table entries are forbidden.

```

define next(#)  $\equiv$  hash[#].lh  { link for coalesced lists }
define text(#)  $\equiv$  hash[#].rh  { string number for control sequence name }
define hash_is_full  $\equiv$  (hash_used = hash_base)  { test if all positions are occupied }
define font_id_text(#)  $\equiv$  text(font_id_base + #)  { a frozen font identifier’s name }

```

⟨Global variables 13⟩ +≡

```

hash:  $\uparrow$ two_halves;  { the hash table }
yhash:  $\uparrow$ two_halves;  { auxiliary pointer for freeing hash }
hash_used: pointer;  { allocation pointer for hash }
hash_extra: pointer;  { hash_extra = hash above eqtb_size }
hash_top: pointer;  { maximum of the hash array }
eqtb_top: pointer;  { maximum of the eqtb }
hash_high: pointer;  { pointer to next high hash location }
no_new_control_sequence: boolean;  { are new identifiers legal? }
cs_count: integer;  { total number of known identifiers }

```

**263.** ⟨Set initial values of key variables 21⟩ +≡

```

no_new_control_sequence  $\leftarrow$  true;  { new identifiers are usually forbidden }

```

**264.** ⟨Initialize table entries (done by INITEX only) 170⟩ +≡

```

hash_used  $\leftarrow$  frozen_control_sequence;  { nothing is used }
hash_high  $\leftarrow$  0; cs_count  $\leftarrow$  0; eq_type(frozen_dont_expand)  $\leftarrow$  dont_expand;
text(frozen_dont_expand)  $\leftarrow$  "notexpanded:";

```

**265.** Here is the subroutine that searches the hash table for an identifier that matches a given string of length  $l > 1$  appearing in  $buffer[j .. (j + l - 1)]$ . If the identifier is found, the corresponding hash table address is returned. Otherwise, if the global variable *no\_new\_control\_sequence* is *true*, the dummy address *undefined\_control\_sequence* is returned. Otherwise the identifier is inserted into the hash table and its location is returned.

```

function id_lookup(j, l : integer): pointer; { search the hash table }
  label found; { go here if you found it }
  var h: integer; { hash code }
      d: integer; { number of characters in incomplete current string }
      p: pointer; { index in hash array }
      k: pointer; { index in buffer array }
  begin ⟨ Compute the hash code h 267 ⟩;
  p ← h + hash_base; { we start searching here; note that  $0 \leq h < hash\_prime$  }
  loop begin if text(p) > 0 then
    if length(text(p)) = l then
      if str_eq_buf(text(p), j) then goto found;
    if next(p) = 0 then
      begin if no_new_control_sequence then p ← undefined_control_sequence
      else ⟨ Insert a new control sequence after p, then make p point to it 266 ⟩;
      goto found;
      end;
      p ← next(p);
    end;
found: id_lookup ← p;
end;

```

```

266. ⟨ Insert a new control sequence after p, then make p point to it 266 ⟩ ≡
  begin if text(p) > 0 then
    begin if hash_high < hash_extra then
      begin incr(hash_high); next(p) ← hash_high + eqtb_size; p ← hash_high + eqtb_size;
      end
    else begin repeat if hash_is_full then overflow("hash_size", hash_size + hash_extra);
      decr(hash_used);
      until text(hash_used) = 0; { search for an empty location in hash }
      next(p) ← hash_used; p ← hash_used;
      end;
    end;
    str_room(l); d ← cur_length;
    while pool_ptr > str_start[str_ptr] do
      begin decr(pool_ptr); str_pool[pool_ptr + l] ← str_pool[pool_ptr];
      end; { move current string up to make room for another }
    for k ← j to j + l - 1 do append_char(buffer[k]);
    text(p) ← make_string; pool_ptr ← pool_ptr + d;
    stat incr(cs_count); tats
  end

```

This code is used in section 265.

**267.** The value of *hash\_prime* should be roughly 85% of *hash\_size*, and it should be a prime number. The theory of hashing tells us to expect fewer than two table probes, on the average, when the search is successful. [See J. S. Vitter, *Journal of the ACM* **30** (1983), 231–258.]

```

⟨Compute the hash code h 267⟩ ≡
  h ← buffer[j];
  for k ← j + 1 to j + l - 1 do
    begin h ← h + h + buffer[k];
    while h ≥ hash_prime do h ← h - hash_prime;
    end

```

This code is used in section 265.

**268.** Single-character control sequences do not need to be looked up in a hash table, since we can use the character code itself as a direct address. The procedure *print\_cs* prints the name of a control sequence, given a pointer to its address in *eqtb*. A space is printed after the name unless it is a single nonletter or an active character. This procedure might be invoked with invalid data, so it is “extra robust.” The individual characters must be printed one at a time using *print*, since they may be unprintable.

```

⟨Basic printing procedures 58⟩ +≡
procedure print_cs(p : integer); { prints a purported control sequence }
  begin if p < hash_base then { single character }
    if p ≥ single_base then
      if p = null_cs then
        begin print_esc("csname"); print_esc("endcsname");
        end
      else begin print_esc(p - single_base);
        if cat_code(p - single_base) = letter then print_char(" ");
        end
      else if p < active_base then print_esc("IMPOSSIBLE.")
        else print(p - active_base)
      else if ((p ≥ undefined_control_sequence) ∧ (p ≤ eqtb_size)) ∨ (p > eqtb_top) then
        print_esc("IMPOSSIBLE.")
      else if (text(p) ≥ str_ptr) then print_esc("NONEXISTENT.")
        else begin print_esc(text(p)); print_char(" ");
        end;
    end;

```

**269.** Here is a similar procedure; it avoids the error checks, and it never prints a space after the control sequence.

```

⟨Basic printing procedures 58⟩ +≡
procedure sprint_cs(p : pointer); { prints a control sequence }
  begin if p < hash_base then
    if p < single_base then print(p - active_base)
    else if p < null_cs then print_esc(p - single_base)
      else begin print_esc("csname"); print_esc("endcsname");
      end
    else print_esc(text(p));
  end;

```

**270.** We need to put T<sub>E</sub>X's "primitive" control sequences into the hash table, together with their command code (which will be the *eq\_type*) and an operand (which will be the *equiv*). The *primitive* procedure does this, in a way that no T<sub>E</sub>X user can. The global value *cur\_val* contains the new *eqtb* pointer after *primitive* has acted.

```

init procedure primitive(s : str_number; c : quarterword; o : halfword);
var k: pool_pointer; { index into str_pool }
     j: small_number; { index into buffer }
     l: small_number; { length of the string }
begin if s < 256 then cur_val ← s + single_base
else begin k ← str_start[s]; l ← str_start[s + 1] - k; { we will move s into the (empty) buffer }
     for j ← 0 to l - 1 do buffer[j] ← so(str_pool[k + j]);
     cur_val ← id_lookup(0, l); { no_new_control_sequence is false }
     flush_string; text(cur_val) ← s; { we don't want to have the string twice }
     end;
eq_level(cur_val) ← level_one; eq_type(cur_val) ← c; equiv(cur_val) ← o;
end;
tini

```

**271.** Many of T<sub>E</sub>X's primitives need no *equiv*, since they are identifiable by their *eq\_type* alone. These primitives are loaded into the hash table as follows:

⟨Put each of T<sub>E</sub>X's primitives into the hash table 232⟩ +≡

```

primitive("␣", ex_space, 0);
primitive("/", ital_corr, 0);
primitive("accent", accent, 0);

vcenter: print_esc("vcenter");
vrule: print_esc("vrule");

```

**273.** We will deal with the other primitives later, at some point in the program where their *eq\_type* and *equiv* values are more meaningful. For example, the primitives for math mode will be loaded when we consider the routines that deal with formulas. It is easy to find where each particular primitive was treated by looking in the index at the end; for example, the section where "radical" entered *eqtb* is listed under '\radical primitive'. (Primitives consisting of a single nonalphabetic character, like '\/', are listed under 'Single-character primitives'.)

Meanwhile, this is a convenient place to catch up on something we were unable to do before the hash table was defined:

```
<Print the font identifier for font(p) 273> ≡  
  print_esc(font_id_text(font(p)))
```

This code is used in sections 180 and 182.

**274. Saving and restoring equivalents.** The nested structure provided by ‘{...}’ groups in T<sub>E</sub>X means that *eqtb* entries valid in outer groups should be saved and restored later if they are overridden inside the braces. When a new *eqtb* value is being assigned, the program therefore checks to see if the previous entry belongs to an outer level. In such a case, the old value is placed on the *save\_stack* just before the new value enters *eqtb*. At the end of a grouping level, i.e., when the right brace is sensed, the *save\_stack* is used to restore the outer values, and the inner ones are destroyed.

Entries on the *save\_stack* are of type *memory\_word*. The top item on this stack is *save\_stack*[*p*], where  $p = \text{save\_ptr} - 1$ ; it contains three fields called *save\_type*, *save\_level*, and *save\_index*, and it is interpreted in one of four ways:

- 1) If  $\text{save\_type}(p) = \text{restore\_old\_value}$ , then  $\text{save\_index}(p)$  is a location in *eqtb* whose current value should be destroyed at the end of the current group and replaced by *save\_stack*[ $p - 1$ ]. Furthermore if  $\text{save\_index}(p) \geq \text{int\_base}$ , then  $\text{save\_level}(p)$  should replace the corresponding entry in *xeq\_level*.
- 2) If  $\text{save\_type}(p) = \text{restore\_zero}$ , then  $\text{save\_index}(p)$  is a location in *eqtb* whose current value should be destroyed at the end of the current group, when it should be replaced by the current value of *eqtb*[*undefined\_control\_sequence*].
- 3) If  $\text{save\_type}(p) = \text{insert\_token}$ , then  $\text{save\_index}(p)$  is a token that should be inserted into T<sub>E</sub>X’s input when the current group ends.
- 4) If  $\text{save\_type}(p) = \text{level\_boundary}$ , then  $\text{save\_level}(p)$  is a code explaining what kind of group we were previously in, and  $\text{save\_index}(p)$  points to the level boundary word at the bottom of the entries for that group.

```

define save_type(#)  $\equiv$  save_stack[#].hh.b0  { classifies a save_stack entry }
define save_level(#)  $\equiv$  save_stack[#].hh.b1  { saved level for regions 5 and 6, or group code }
define save_index(#)  $\equiv$  save_stack[#].hh.rh  { eqtb location or token or save_stack location }
define restore_old_value = 0  { save_type when a value should be restored later }
define restore_zero = 1  { save_type when an undefined entry should be restored }
define insert_token = 2  { save_type when a token is being saved for later use }
define level_boundary = 3  { save_type corresponding to beginning of group }

```

**275.** Here are the group codes that are used to discriminate between different kinds of groups. They allow TeX to decide what special actions, if any, should be performed when a group ends.

Some groups are not supposed to be ended by right braces. For example, the ‘\$’ that begins a math formula causes a *math\_shift\_group* to be started, and this should be terminated by a matching ‘\$’. Similarly, a group that starts with `\left` should end with `\right`, and one that starts with `\begingroup` should end with `\endgroup`.

```

define bottom_level = 0 {group code for the outside world}
define simple_group = 1 {group code for local structure only}
define hbox_group = 2 {code for ‘\hbox{...}’}
define adjusted_hbox_group = 3 {code for ‘\hbox{...}’ in vertical mode}
define vbox_group = 4 {code for ‘\vbox{...}’}
define vtop_group = 5 {code for ‘\vtop{...}’}
define align_group = 6 {code for ‘\halign{...}’, ‘\valign{...}’}
define no_align_group = 7 {code for ‘\noalign{...}’}
define output_group = 8 {code for output routine}
define math_group = 9 {code for, e.g., ‘^{...}’}
define disc_group = 10 {code for ‘\discretionary{...}{...}{...}’}
define insert_group = 11 {code for ‘\insert{...}’, ‘\vadjust{...}’}
define vcenter_group = 12 {code for ‘\vcenter{...}’}
define math_choice_group = 13 {code for ‘\mathchoice{...}{...}{...}{...}’}
define semi_simple_group = 14 {code for ‘\begingroup... \endgroup’}
define math_shift_group = 15 {code for ‘$...$’}
define math_left_group = 16 {code for ‘\left... \right’}
define max_group_code = 16

```

⟨Types in the outer block 18⟩ +≡

```

group_code = 0 .. max_group_code; {save_level for a level boundary}

```

**276.** The global variable *cur\_group* keeps track of what sort of group we are currently in. Another global variable, *cur\_boundary*, points to the topmost *level\_boundary* word. And *cur\_level* is the current depth of nesting. The routines are designed to preserve the condition that no entry in the *save\_stack* or in *eqtb* ever has a level greater than *cur\_level*.

**277.** ⟨Global variables 13⟩ +≡

*save\_stack*: ↑*memory\_word*;

*save\_ptr*: 0 .. *save\_size*; {first unused entry on *save\_stack*}

*max\_save\_stack*: 0 .. *save\_size*; {maximum usage of save stack}

*cur\_level*: *quarterword*; {current nesting level for groups}

*cur\_group*: *group\_code*; {current group type}

*cur\_boundary*: 0 .. *save\_size*; {where the current level begins}

**278.** At this time it might be a good idea for the reader to review the introduction to *eqtb* that was given above just before the long lists of parameter names. Recall that the “outer level” of the program is *level\_one*, since undefined control sequences are assumed to be “defined” at *level\_zero*.

⟨Set initial values of key variables 21⟩ +≡

```

save_ptr ← 0; cur_level ← level_one; cur_group ← bottom_level; cur_boundary ← 0; max_save_stack ← 0;

```

**279.** The following macro is used to test if there is room for up to six more entries on *save\_stack*. By making a conservative test like this, we can get by with testing for overflow in only a few places.

```
define check_full_save_stack ≡
  if save_ptr > max_save_stack then
    begin max_save_stack ← save_ptr;
    if max_save_stack > save_size - 6 then overflow("save_size", save_size);
  end
```

**280.** Procedure *new\_save\_level* is called when a group begins. The argument is a group identification code like ‘*hbox\_group*’. After calling this routine, it is safe to put five more entries on *save\_stack*.

In some cases integer-valued items are placed onto the *save\_stack* just below a *level\_boundary* word, because this is a convenient place to keep information that is supposed to “pop up” just when the group has finished. For example, when ‘`\hbox to 100pt{...}`’ is being treated, the 100pt dimension is stored on *save\_stack* just before *new\_save\_level* is called.

We use the notation *saved(k)* to stand for an integer item that appears in location *save\_ptr + k* of the save stack.

```
define saved(#) ≡ save_stack[save_ptr + #].int
procedure new_save_level(c : group_code); { begin a new level of grouping }
  begin check_full_save_stack; save_type(save_ptr) ← level_boundary; save_level(save_ptr) ← cur_group;
  save_index(save_ptr) ← cur_boundary;
  if cur_level = max_quarterword then
    overflow("grouping_levels", max_quarterword - min_quarterword);
    { quit if (cur_level + 1) is too big to be stored in eqtb }
  cur_boundary ← save_ptr; incr(cur_level); incr(save_ptr); cur_group ← c;
  end;
```

**281.** Just before an entry of *eqtb* is changed, the following procedure should be called to update the other data structures properly. It is important to keep in mind that reference counts in *mem* include references from within *save\_stack*, so these counts must be handled carefully.

```
procedure eq_destroy(w : memory_word); { gets ready to forget w }
  var q : pointer; { equiv field of w }
  begin case eq_type_field(w) of
    call, long_call, outer_call, long_outer_call: delete_token_ref(equiv_field(w));
    glue_ref: delete_glue_ref(equiv_field(w));
    shape_ref: begin q ← equiv_field(w); { we need to free a \parshape block }
      if q ≠ null then free_node(q, info(q) + info(q) + 1);
      end; { such a block is 2n + 1 words long, where n = info(q) }
    box_ref: flush_node_list(equiv_field(w));
  othercases do_nothing
  endcases;
  end;
```

**282.** To save a value of *eqtb[p]* that was established at level *l*, we can use the following subroutine.

```
procedure eq_save(p : pointer; l : quarterword); { saves eqtb[p] }
  begin check_full_save_stack;
  if l = level_zero then save_type(save_ptr) ← restore_zero
  else begin save_stack[save_ptr] ← eqtb[p]; incr(save_ptr); save_type(save_ptr) ← restore_old_value;
  end;
  save_level(save_ptr) ← l; save_index(save_ptr) ← p; incr(save_ptr);
  end;
```

**283.** The procedure *eq\_define* defines an *eqtb* entry having specified *eq\_type* and *equiv* fields, and saves the former value if appropriate. This procedure is used only for entries in the first four regions of *eqtb*, i.e., only for entries that have *eq\_type* and *equiv* fields. After calling this routine, it is safe to put four more entries on *save\_stack*, provided that there was room for four more entries before the call, since *eq\_save* makes the necessary test.

```
procedure eq_define(p : pointer; t : quarterword; e : halfword); { new data for eqtb }
  begin if eq_level(p) = cur_level then eq_destroy(eqtb[p])
  else if cur_level > level_one then eq_save(p, eq_level(p));
    eq_level(p) ← cur_level; eq_type(p) ← t; equiv(p) ← e;
  end;
```

**284.** The counterpart of *eq\_define* for the remaining (fullword) positions in *eqtb* is called *eq\_word\_define*. Since  $xeq\_level[p] \geq level\_one$  for all *p*, a 'restore\_zero' will never be used in this case.

```
procedure eq_word_define(p : pointer; w : integer);
  begin if xeq_level[p] ≠ cur_level then
    begin eq_save(p, xeq_level[p]); xeq_level[p] ← cur_level;
    end;
  eqtb[p].int ← w;
  end;
```

**285.** The *eq\_define* and *eq\_word\_define* routines take care of local definitions. Global definitions are done in almost the same way, but there is no need to save old values, and the new value is associated with *level\_one*.

```
procedure geq_define(p : pointer; t : quarterword; e : halfword); { global eq_define }
  begin eq_destroy(eqtb[p]); eq_level(p) ← level_one; eq_type(p) ← t; equiv(p) ← e;
  end;
```

```
procedure geq_word_define(p : pointer; w : integer); { global eq_word_define }
  begin eqtb[p].int ← w; xeq_level[p] ← level_one;
  end;
```

**286.** Subroutine *save\_for\_after* puts a token on the stack for save-keeping.

```
procedure save_for_after(t : halfword);
  begin if cur_level > level_one then
    begin check_full_save_stack; save_type(save_ptr) ← insert_token; save_level(save_ptr) ← level_zero;
    save_index(save_ptr) ← t; incr(save_ptr);
    end;
  end;
```

**287.** The *unsave* routine goes the other way, taking items off of *save\_stack*. This routine takes care of restoration when a level ends; everything belonging to the topmost group is cleared off of the save stack.

⟨Declare the procedure called *restore\_trace* 290⟩

```
procedure back_input; forward;
procedure unsave; { pops the top level off the save stack }
  label done;
  var p: pointer; { position to be restored }
    l: quarterword; { saved level, if in fullword regions of eqtb }
    t: halfword; { saved value of cur_tok }
  begin if cur_level > level_one then
    begin decr(cur_level); ⟨Clear off top level from save_stack 288⟩;
    end
  else confusion("curlevel"); { unsave is not used when cur_group = bottom_level }
  end;
```

**288.**  $\langle$  Clear off top level from *save\_stack* 288  $\rangle \equiv$

```

loop begin decr(save_ptr);
  if save_type(save_ptr) = level_boundary then goto done;
  p  $\leftarrow$  save_index(save_ptr);
  if save_type(save_ptr) = insert_token then  $\langle$  Insert token p into TEX's input 332  $\rangle$ 
  else begin if save_type(save_ptr) = restore_old_value then
    begin l  $\leftarrow$  save_level(save_ptr); decr(save_ptr);
    end
    else save_stack[save_ptr]  $\leftarrow$  eqtb[undefined_control_sequence];
     $\langle$  Store save_stack[save_ptr] in eqtb[p], unless eqtb[p] holds a global value 289  $\rangle$ ;
    end;
  end;
done: cur_group  $\leftarrow$  save_level(save_ptr); cur_boundary  $\leftarrow$  save_index(save_ptr)

```

This code is used in section 287.

**289.** A global definition, which sets the level to *level\_one*, will not be undone by *unsave*. If at least one global definition of *eqtb*[*p*] has been carried out within the group that just ended, the last such definition will therefore survive.

$\langle$  Store *save\_stack*[*save\_ptr*] in *eqtb*[*p*], unless *eqtb*[*p*] holds a global value 289  $\rangle \equiv$

```

if (p < int_base)  $\vee$  (p > eqtb_size) then
  if eq_level(p) = level_one then
    begin eq_destroy(save_stack[save_ptr]); { destroy the saved value }
    stat if tracing_restores > 0 then restore_trace(p, "retaining");
    tats
    end
  else begin eq_destroy(eqtb[p]); { destroy the current value }
    eqtb[p]  $\leftarrow$  save_stack[save_ptr]; { restore the saved value }
    stat if tracing_restores > 0 then restore_trace(p, "restoring");
    tats
    end
  else if xeq_level[p]  $\neq$  level_one then
    begin eqtb[p]  $\leftarrow$  save_stack[save_ptr]; xeq_level[p]  $\leftarrow$  l;
    stat if tracing_restores > 0 then restore_trace(p, "restoring");
    tats
    end
  else begin stat if tracing_restores > 0 then restore_trace(p, "retaining");
  tats
  end

```

This code is used in section 288.

**290.**  $\langle$  Declare the procedure called *restore\_trace* 290  $\rangle \equiv$

```

stat procedure restore_trace(p : pointer; s : str_number); { eqtb[p] has just been restored or retained }
begin begin_diagnostic; print_char("{"); print(s); print_char("□"); show_eqtb(p); print_char("}");
end_diagnostic(false);
end;
tats

```

This code is used in section 287.

**291.** When looking for possible pointers to a memory location, it is helpful to look for references from *eqtb* that might be waiting on the save stack. Of course, we might find spurious pointers too; but this routine is merely an aid when debugging, and at such times we are grateful for any scraps of information, even if they prove to be irrelevant.

```

⟨ Search save_stack for equivalents that point to p 291 ⟩ ≡
  if save_ptr > 0 then
    for q ← 0 to save_ptr - 1 do
      begin if equiv_field(save_stack[q]) = p then
        begin print_nl("SAVE("); print_int(q); print_char(")");
        end;
      end
    end

```

This code is used in section 178.

**292.** Most of the parameters kept in *eqtb* can be changed freely, but there's an exception: The magnification should not be used with two different values during any TEX job, since a single magnification is applied to an entire run. The global variable *mag\_set* is set to the current magnification whenever it becomes necessary to "freeze" it at a particular value.

```

⟨ Global variables 13 ⟩ +≡
mag_set: integer; { if nonzero, this magnification should be used henceforth }

```

**293.** ⟨ Set initial values of key variables 21 ⟩ +≡  
*mag\_set* ← 0;

**294.** The *prepare\_mag* subroutine is called whenever TEX wants to use *mag* for magnification.

```

procedure prepare_mag;
  begin if (mag_set > 0) ∧ (mag ≠ mag_set) then
    begin print_err("Incompatible_magnification"); print_int(mag); print(");");
    print_nl("the_previous_value_will_be_retained");
    help2("I_can_handle_only_one_magnification_ratio_per_job. So I've")
    ("reverted_to_the_magnification_you_used_earlier_on_this_run.");
    int_error(mag_set); geq_word_define(int_base + mag_code, mag_set); { mag ← mag_set }
    end;
  if (mag ≤ 0) ∨ (mag > 32768) then
    begin print_err("Illegal_magnification_has_been_changed_to_1000");
    help1("The_magnification_ratio_must_be_between_1_and_32768."); int_error(mag);
    geq_word_define(int_base + mag_code, 1000);
    end;
  mag_set ← mag;
end;

```

**295. Token lists.** A T<sub>E</sub>X token is either a character or a control sequence, and it is represented internally in one of two ways: (1) A character whose ASCII code number is  $c$  and whose command code is  $m$  is represented as the number  $2^8m + c$ ; the command code is in the range  $1 \leq m \leq 14$ . (2) A control sequence whose *eqtb* address is  $p$  is represented as the number  $cs\_token\_flag + p$ . Here  $cs\_token\_flag = 2^{12} - 1$  is larger than  $2^8m + c$ , yet it is small enough that  $cs\_token\_flag + p < max\_halfword$ ; thus, a token fits comfortably in a halfword.

A token  $t$  represents a *left\_brace* command if and only if  $t < left\_brace\_limit$ ; it represents a *right\_brace* command if and only if we have  $left\_brace\_limit \leq t < right\_brace\_limit$ ; and it represents a *match* or *end\_match* command if and only if  $match\_token \leq t \leq end\_match\_token$ . The following definitions take care of these token-oriented constants and a few others.

```

define cs_token_flag ≡ "FFFF" { amount added to the eqtb location in a token that stands for a control
sequence; is a multiple of 256, less 1 }
define left_brace_token = '0400 { 28 · left_brace }
define left_brace_limit = '1000 { 28 · (left_brace + 1) }
define right_brace_token = '1000 { 28 · right_brace }
define right_brace_limit = '1400 { 28 · (right_brace + 1) }
define math_shift_token = '1400 { 28 · math_shift }
define tab_token = '2000 { 28 · tab_mark }
define out_param_token = '2400 { 28 · out_param }
define space_token = '5040 { 28 · spacer + "□" }
define letter_token = '5400 { 28 · letter }
define other_token = '6000 { 28 · other_char }
define match_token = '6400 { 28 · match }
define end_match_token = '7000 { 28 · end_match }

```

**296.** ⟨ Check the “constant” values for consistency 14 ⟩ +≡  
**if**  $cs\_token\_flag + eqtb\_size + hash\_extra > max\_halfword$  **then**  $bad \leftarrow 21$ ;  
**if**  $(hash\_offset < 0) \vee (hash\_offset > hash\_base)$  **then**  $bad \leftarrow 42$ ;

**297.** A token list is a singly linked list of one-word nodes in *mem*, where each word contains a token and a link. Macro definitions, output-routine definitions, marks, `\write` texts, and a few other things are remembered by T<sub>E</sub>X in the form of token lists, usually preceded by a node with a reference count in its *token\_ref\_count* field. The token stored in location *p* is called *info(p)*.

Three special commands appear in the token lists of macro definitions. When *m* = *match*, it means that T<sub>E</sub>X should scan a parameter for the current macro; when *m* = *end\_match*, it means that parameter matching should end and T<sub>E</sub>X should start reading the macro text; and when *m* = *out\_param*, it means that T<sub>E</sub>X should insert parameter number *c* into the text at this point.

The enclosing { and } characters of a macro definition are omitted, but the final right brace of an output routine is included at the end of its token list.

Here is an example macro definition that illustrates these conventions. After T<sub>E</sub>X processes the text

```
\def\mac a#1#2 \b {#1\ -a ##1#2 #2}
```

the definition of `\mac` is represented as a token list containing

```
(reference count), letter a, match #, match #, spacer ␣, \b, end_match,
out_param 1, \ -, letter a, spacer ␣, mac_param #, other_char 1,
out_param 2, spacer ␣, out_param 2.
```

The procedure *scan\_toks* builds such token lists, and *macro\_call* does the parameter matching.

Examples such as

```
\def\m{\def\m{a}␣b}
```

explain why reference counts would be needed even if T<sub>E</sub>X had no `\let` operation: When the token list for `\m` is being read, the redefinition of `\m` changes the *eqtb* entry before the token list has been fully consumed, so we dare not simply destroy a token list when its control sequence is being redefined.

If the parameter-matching part of a definition ends with `{#}`, the corresponding token list will have `{` just before the *end\_match* and also at the very end. The first `{` is used to delimit the parameter; the second one keeps the first from disappearing.

**298.** The procedure *show\_token\_list*, which prints a symbolic form of the token list that starts at a given node *p*, illustrates these conventions. The token list being displayed should not begin with a reference count. However, the procedure is intended to be robust, so that if the memory links are awry or if *p* is not really a pointer to a token list, nothing catastrophic will happen.

An additional parameter *q* is also given; this parameter is either null or it points to a node in the token list where a certain magic computation takes place that will be explained later. (Basically, *q* is non-null when we are printing the two-line context information at the time of an error message; *q* marks the place corresponding to where the second line should begin.)

For example, if *p* points to the node containing the first **a** in the token list above, then *show\_token\_list* will print the string

```
‘a#1#2_\b_\->#1\ -a_\##1#2_\#2’;
```

and if *q* points to the node containing the second **a**, the magic computation will be performed just before the second **a** is printed.

The generation will stop, and ‘\ETC.’ will be printed, if the length of printing exceeds a given limit *l*. Anomalous entries are printed in the form of control sequences that are not followed by a blank space, e.g., ‘\BAD.’; this cannot be confused with actual control sequences because a real control sequence named **BAD** would come out ‘\BAD\_’.

⟨Declare the procedure called *show\_token\_list* 298⟩ ≡

```
procedure show_token_list(p, q : integer; l : integer);
  label exit;
  var m, c: integer; { pieces of a token }
      match_chr: ASCII_code; { character used in a ‘match’ }
      n: ASCII_code; { the highest parameter number, as an ASCII digit }
  begin match_chr ← "#"; n ← "0"; tally ← 0;
  while (p ≠ null) ∧ (tally < l) do
    begin if p = q then ⟨Do magic computation 326⟩;
      ⟨Display token p, and return if there are problems 299⟩;
      p ← link(p);
    end;
  if p ≠ null then print_esc("ETC.");
exit: end;
```

This code is used in section 120.

**299.** ⟨Display token *p*, and **return** if there are problems 299⟩ ≡

```
if (p < hi_mem_min) ∨ (p > mem_end) then
  begin print_esc("CLOBBED."); return;
  end;
if info(p) ≥ cs_token_flag then print_cs(info(p) - cs_token_flag) { wchar_token }
else begin if check_kanji(info(p)) then { wchar_token }
  begin m ← kcat_code(kcat_codekey(info(p))); c ← info(p);
  end
  else begin m ← Hi(info(p)); c ← Lo(info(p));
  end;
  if (m < kanji) ∧ (c > 256) then print_esc("BAD.")
  else ⟨Display the token (m, c) 300⟩;
  end
```

This code is used in section 298.

**300.** The procedure usually “learns” the character code used for macro parameters by seeing one in a *match* command before it runs into any *out\_param* commands.

```

⟨Display the token (m, c) 300⟩ ≡
case m of
  kanji, kana, other_kchar: print_kanji(KANJI(c));
  left_brace, right_brace, math_shift, tab_mark, sup_mark, sub_mark, spacer, letter, other_char: print(c);
  mac_param: begin print(c); print(c);
    end;
  out_param: begin print(match_chr);
    if c ≤ 9 then print_char(c + "0")
    else begin print_char("!"); return;
    end;
  end;
  match: begin match_chr ← c; print(c); incr(n); print_char(n);
    if n > "9" then return;
    end;
  end_match: print("->");
  othercases print_esc("BAD. ")
endcases

```

This code is used in section 299.

**301.** Here’s the way we sometimes want to display a token list, given a pointer to its reference count; the pointer may be null.

```

procedure token_show(p : pointer);
  begin if p ≠ null then show_token_list(link(p), null, 10000000);
  end;

```

**302.** The *print\_meaning* subroutine displays *cur\_cmd* and *cur\_chr* in symbolic form, including the expansion of a macro or mark.

```

procedure print_meaning;
  begin print_cmd_chr(cur_cmd, cur_chr);
  if cur_cmd ≥ call then
    begin print_char(":"); print_ln; token_show(cur_chr);
    end
  else if cur_cmd = top_bot_mark then
    begin print_char(":"); print_ln; token_show(cur_mark[cur_chr]);
    end;
  end;

```

**303. Introduction to the syntactic routines.** Let's pause a moment now and try to look at the Big Picture. The T<sub>E</sub>X program consists of three main parts: syntactic routines, semantic routines, and output routines. The chief purpose of the syntactic routines is to deliver the user's input to the semantic routines, one token at a time. The semantic routines act as an interpreter responding to these tokens, which may be regarded as commands. And the output routines are periodically called on to convert box-and-glue lists into a compact set of instructions that will be sent to a typesetter. We have discussed the basic data structures and utility routines of T<sub>E</sub>X, so we are good and ready to plunge into the real activity by considering the syntactic routines.

Our current goal is to come to grips with the *get\_next* procedure, which is the keystone of T<sub>E</sub>X's input mechanism. Each call of *get\_next* sets the value of three variables *cur\_cmd*, *cur\_chr*, and *cur\_cs*, representing the next input token.

*cur\_cmd* denotes a command code from the long list of codes given above;  
*cur\_chr* denotes a character code or other modifier of the command code;  
*cur\_cs* is the *eqtb* location of the current control sequence,  
 if the current token was a control sequence, otherwise it's zero.

Underlying this external behavior of *get\_next* is all the machinery necessary to convert from character files to tokens. At a given time we may be only partially finished with the reading of several files (for which `\input` was specified), and partially finished with the expansion of some user-defined macros and/or some macro parameters, and partially finished with the generation of some text in a template for `\halign`, and so on. When reading a character file, special characters must be classified as math delimiters, etc.; comments and extra blank spaces must be removed, paragraphs must be recognized, and control sequences must be found in the hash table. Furthermore there are occasions in which the scanning routines have looked ahead for a word like 'plus' but only part of that word was found, hence a few characters must be put back into the input and scanned again.

To handle these situations, which might all be present simultaneously, T<sub>E</sub>X uses various stacks that hold information about the incomplete activities, and there is a finite state control for each level of the input mechanism. These stacks record the current state of an implicitly recursive process, but the *get\_next* procedure is not recursive. Therefore it will not be difficult to translate these algorithms into low-level languages that do not support recursion.

⟨Global variables 13⟩ +≡  
*cur\_cmd*: *eight\_bits*; { current command set by *get\_next* }  
*cur\_chr*: *halfword*; { operand of current command }  
*cur\_cs*: *pointer*; { control sequence found here, zero if none found }  
*cur\_tok*: *halfword*; { packed representative of *cur\_cmd* and *cur\_chr* }

**304.** The *print\_cmd\_chr* routine prints a symbolic interpretation of a command code and its modifier. This is used in certain ‘You can’t’ error messages, and in the implementation of diagnostic routines like `\show`.

The body of *print\_cmd\_chr* is a rather tedious listing of print commands, and most of it is essentially an inverse to the *primitive* routine that enters a TeX primitive into *eqtb*. Therefore much of this procedure appears elsewhere in the program, together with the corresponding *primitive* calls.

```

define chr_cmd(#) ≡
    begin print(#); print_ASCII(chr_code);
    end

⟨Declare the procedure called print_cmd_chr 304⟩ ≡
procedure print_cmd_chr(cmd : quarterword; chr_code : halfword);
    begin case cmd of
        left_brace: chr_cmd("begin-group_character_");
        right_brace: chr_cmd("end-group_character_");
        math_shift: chr_cmd("math_shift_character_");
        mac_param: chr_cmd("macro_parameter_character_");
        sup_mark: chr_cmd("superscript_character_");
        sub_mark: chr_cmd("subscript_character_");
        endv: print("end_of_alignment_template");
        spacer: chr_cmd("blank_space_");
        letter: chr_cmd("the_letter_");
        other_char: chr_cmd("the_character_");
        kanji, kana, other_kchar: begin print("kanji_character_"); print_kanji(KANJI(chr_code));
        end;
    ⟨Cases of print_cmd_chr for symbolic printing of primitives 233⟩
    othercases print("[unknown_command_code!]")
    endcases;
end;

```

This code is used in section 258.

**305.** Here is a procedure that displays the current command.

```

procedure show_cur_cmd_chr;
    begin begin_diagnostic; print_nl("{");
    if mode ≠ shown_mode then
        begin print_mode(mode); print(":_"); shown_mode ← mode;
        end;
    print_cmd_chr(cur_cmd, cur_chr); print_char("}"); end_diagnostic(false);
end;

```

**306. Input stacks and states.** This implementation of T<sub>E</sub>X uses two different conventions for representing sequential stacks.

- 1) If there is frequent access to the top entry, and if the stack is essentially never empty, then the top entry is kept in a global variable (even better would be a machine register), and the other entries appear in the array *stack*[0 .. (*ptr* - 1)]. For example, the semantic stack described above is handled this way, and so is the input stack that we are about to study.
- 2) If there is infrequent top access, the entire stack contents are in the array *stack*[0 .. (*ptr* - 1)]. For example, the *save\_stack* is treated this way, as we have seen.

The state of T<sub>E</sub>X's input mechanism appears in the input stack, whose entries are records with six fields, called *state*, *index*, *start*, *loc*, *limit*, and *name*. This stack is maintained with convention (1), so it is declared in the following way:

```
⟨Types in the outer block 18⟩ +≡
  in_state_record = record state_field, index_field: quarterword;
                    start_field, loc_field, limit_field, name_field: halfword;
                    end;
```

```
307. ⟨Global variables 13⟩ +≡
input_stack: ↑in_state_record;
input_ptr: 0 .. stack_size; { first unused location of input_stack }
max_in_stack: 0 .. stack_size; { largest value of input_ptr when pushing }
cur_input: in_state_record; { the “top” input state, according to convention (1) }
```

**308.** We've already defined the special variable *loc* ≡ *cur\_input.loc\_field* in our discussion of basic input-output routines. The other components of *cur\_input* are defined in the same way:

```
define state ≡ cur_input.state_field { current scanner state }
define index ≡ cur_input.index_field { reference for buffer information }
define start ≡ cur_input.start_field { starting position in buffer }
define limit ≡ cur_input.limit_field { end of current line in buffer }
define name ≡ cur_input.name_field { name of the current file }
```

**309.** Let's look more closely now at the control variables (*state*, *index*, *start*, *loc*, *limit*, *name*), assuming that T<sub>E</sub>X is reading a line of characters that have been input from some file or from the user's terminal. There is an array called *buffer* that acts as a stack of all lines of characters that are currently being read from files, including all lines on subsidiary levels of the input stack that are not yet completed. T<sub>E</sub>X will return to the other lines when it is finished with the present input file.

(Incidentally, on a machine with byte-oriented addressing, it might be appropriate to combine *buffer* with the *str\_pool* array, letting the buffer entries grow downward from the top of the string pool and checking that these two tables don't bump into each other.)

The line we are currently working on begins in position *start* of the buffer; the next character we are about to read is *buffer[loc]*; and *limit* is the location of the last character present. If *loc* > *limit*, the line has been completely read. Usually *buffer[limit]* is the *end\_line\_char*, denoting the end of a line, but this is not true if the current line is an insertion that was entered on the user's terminal in response to an error message.

The *name* variable is a string number that designates the name of the current file, if we are reading a text file. It is zero if we are reading from the terminal; it is *n* + 1 if we are reading from input stream *n*, where  $0 \leq n \leq 16$ . (Input stream 16 stands for an invalid stream number; in such cases the input is actually from the terminal, under control of the procedure *read\_toks*.)

The *state* variable has one of three values, when we are scanning such files:

- 1) *state* = *mid\_line* is the normal state.
- 2) *state* = *mid\_kanji* is like *mid\_line*, and internal KANJI string.
- 3) *state* = *skip\_blanks* is like *mid\_line*, but blanks are ignored.
- 4) *state* = *new\_line* is the state at the beginning of a line.

These state values are assigned numeric codes so that if we add the state code to the next character's command code, we get distinct values. For example, '*mid\_line* + *spacer*' stands for the case that a blank space character occurs in the middle of a line when it is not being ignored; after this case is processed, the next value of *state* will be *skip\_blanks*.

```

define mid_line = 1 { state code when scanning a line of characters }
define mid_kanji = 2 + max_char_code { state code when scanning a line of characters }
define skip_blanks = 3 + max_char_code + max_char_code { state code when ignoring blanks }
define new_line = 4 + max_char_code + max_char_code + max_char_code { state code at start of line }

```

**310.** Additional information about the current line is available via the *index* variable, which counts how many lines of characters are present in the buffer below the current level. We have *index* = 0 when reading from the terminal and prompting the user for each line; then if the user types, e.g., ‘\input paper’, we will have *index* = 1 while reading the file `paper.tex`. However, it does not follow that *index* is the same as the input stack pointer, since many of the levels on the input stack may come from token lists. For example, the instruction ‘\input paper’ might occur in a token list.

The global variable *in\_open* is equal to the *index* value of the highest non-token-list level. Thus, the number of partially read lines in the buffer is *in\_open* + 1, and we have *in\_open* = *index* when we are not reading a token list.

If we are not currently reading from the terminal, or from an input stream, we are reading from the file variable *input\_file*[*index*]. We use the notation *terminal\_input* as a convenient abbreviation for *name* = 0, and *cur\_file* as an abbreviation for *input\_file*[*index*].

The global variable *line* contains the line number in the topmost open file, for use in error messages. If we are not reading from the terminal, *line\_stack*[*index*] holds the line number for the enclosing level, so that *line* can be restored when the current file has been read. Line numbers should never be negative, since the negative of the current line number is used to identify the user’s output routine in the *mode\_line* field of the semantic nest entries.

If more information about the input state is needed, it can be included in small arrays like those shown here. For example, the current page or segment number in the input file might be put into a variable *page*, maintained for enclosing levels in ‘*page\_stack*: **array** [1 .. *max\_in\_open*] **of** *integer*’ by analogy with *line\_stack*.

```
define terminal_input ≡ (name = 0) { are we reading from the terminal? }
```

```
define cur_file ≡ input_file[index] { the current alpha_file variable }
```

```
⟨ Global variables 13 ⟩ +≡
```

```
in_open: 0 .. max_in_open; { the number of lines in the buffer, less one }
```

```
open_parens: 0 .. max_in_open; { the number of open text files }
```

```
input_file: ↑alpha_file;
```

```
line: integer; { current line number in the current source file }
```

```
line_stack: ↑integer;
```

```
source_filename_stack: ↑str_number;
```

```
full_source_filename_stack: ↑str_number;
```

**311.** Users of T<sub>E</sub>X sometimes forget to balance left and right braces properly, and one of the ways T<sub>E</sub>X tries to spot such errors is by considering an input file as broken into subfiles by control sequences that are declared to be `\outer`.

A variable called `scanner_status` tells T<sub>E</sub>X whether or not to complain when a subfile ends. This variable has six possible values:

*normal*, means that a subfile can safely end here without incident.

*skipping*, means that a subfile can safely end here, but not a file, because we're reading past some conditional text that was not selected.

*defining*, means that a subfile shouldn't end now because a macro is being defined.

*matching*, means that a subfile shouldn't end now because a macro is being used and we are searching for the end of its arguments.

*aligning*, means that a subfile shouldn't end now because we are not finished with the preamble of an `\halign` or `\valign`.

*absorbing*, means that a subfile shouldn't end now because we are reading a balanced token list for `\message`, `\write`, etc.

If the `scanner_status` is not *normal*, the variable `warning_index` points to the `eqtb` location for the relevant control sequence name to print in an error message.

```

define skipping = 1 { scanner_status when passing conditional text }
define defining = 2 { scanner_status when reading a macro definition }
define matching = 3 { scanner_status when reading macro arguments }
define aligning = 4 { scanner_status when reading an alignment preamble }
define absorbing = 5 { scanner_status when reading a balanced text }

```

⟨Global variables 13⟩ +=

```

scanner_status: normal .. absorbing; { can a subfile end now? }
warning_index: pointer; { identifier relevant to non-normal scanner status }
def_ref: pointer; { reference count of token list being defined }

```

**312.** Here is a procedure that uses `scanner_status` to print a warning message when a subfile has ended, and at certain other crucial times:

⟨Declare the procedure called `runaway` 312⟩ ≡

```

procedure runaway;
  var p: pointer; { head of runaway list }
  begin if scanner_status > skipping then
    begin case scanner_status of
      defining: begin print_nl("Runaway_definition"); p ← def_ref;
        end;
      matching: begin print_nl("Runaway_argument"); p ← temp_head;
        end;
      aligning: begin print_nl("Runaway_preamble"); p ← hold_head;
        end;
      absorbing: begin print_nl("Runaway_text"); p ← def_ref;
        end;
    end; { there are no other cases }
    print_char("?"); print_ln; show_token_list(link(p), null, error_line - 10);
  end;
end;

```

This code is used in section 120.

**313.** However, all this discussion about input state really applies only to the case that we are inputting from a file. There is another important case, namely when we are currently getting input from a token list. In this case *state* = *token\_list*, and the conventions about the other state variables are different:

*loc* is a pointer to the current node in the token list, i.e., the node that will be read next. If *loc* = *null*, the token list has been fully read.

*start* points to the first node of the token list; this node may or may not contain a reference count, depending on the type of token list involved.

*token\_type*, which takes the place of *index* in the discussion above, is a code number that explains what kind of token list is being scanned.

*name* points to the *eqtb* address of the control sequence being expanded, if the current token list is a macro.

*param\_start*, which takes the place of *limit*, tells where the parameters of the current macro begin in the *param\_stack*, if the current token list is a macro.

The *token\_type* can take several values, depending on where the current token list came from:

*parameter*, if a parameter is being scanned;

*u\_template*, if the  $\langle u_j \rangle$  part of an alignment template is being scanned;

*v\_template*, if the  $\langle v_j \rangle$  part of an alignment template is being scanned;

*backed\_up*, if the token list being scanned has been inserted as ‘to be read again’.

*inserted*, if the token list being scanned has been inserted as the text expansion of a  $\backslash\text{count}$  or similar variable;

*macro*, if a user-defined control sequence is being scanned;

*output\_text*, if an  $\backslash\text{output}$  routine is being scanned;

*every\_par\_text*, if the text of  $\backslash\text{everypar}$  is being scanned;

*every\_math\_text*, if the text of  $\backslash\text{everymath}$  is being scanned;

*every\_display\_text*, if the text of  $\backslash\text{everydisplay}$  is being scanned;

*every\_hbox\_text*, if the text of  $\backslash\text{everyhbox}$  is being scanned;

*every\_vbox\_text*, if the text of  $\backslash\text{everyvbox}$  is being scanned;

*every\_job\_text*, if the text of  $\backslash\text{everyjob}$  is being scanned;

*every\_cr\_text*, if the text of  $\backslash\text{everycr}$  is being scanned;

*mark\_text*, if the text of a  $\backslash\text{mark}$  is being scanned;

*write\_text*, if the text of a  $\backslash\text{write}$  is being scanned.

The codes for *output\_text*, *every\_par\_text*, etc., are equal to a constant plus the corresponding codes for token list parameters *output\_routine\_loc*, *every\_par\_loc*, etc. The token list begins with a reference count if and only if *token\_type*  $\geq$  *macro*.

```

define token_list = 0 { state code when scanning a token list }
define token_type  $\equiv$  index { type of current token list }
define param_start  $\equiv$  limit { base of macro parameters in param_stack }
define parameter = 0 { token_type code for parameter }
define u_template = 1 { token_type code for  $\langle u_j \rangle$  template }
define v_template = 2 { token_type code for  $\langle v_j \rangle$  template }
define backed_up = 3 { token_type code for text to be reread }
define inserted = 4 { token_type code for inserted texts }
define macro = 5 { token_type code for defined control sequences }
define output_text = 6 { token_type code for output routines }
define every_par_text = 7 { token_type code for  $\backslash\text{everypar}$  }
define every_math_text = 8 { token_type code for  $\backslash\text{everymath}$  }
define every_display_text = 9 { token_type code for  $\backslash\text{everydisplay}$  }
define every_hbox_text = 10 { token_type code for  $\backslash\text{everyhbox}$  }
define every_vbox_text = 11 { token_type code for  $\backslash\text{everyvbox}$  }
define every_job_text = 12 { token_type code for  $\backslash\text{everyjob}$  }
define every_cr_text = 13 { token_type code for  $\backslash\text{everycr}$  }

```

```

define mark_text = 14 { token_type code for \topmark, etc. }
define write_text = 15 { token_type code for \write }

```

**314.** The *param\_stack* is an auxiliary array used to hold pointers to the token lists for parameters at the current level and subsidiary levels of input. This stack is maintained with convention (2), and it grows at a different rate from the others.

```

⟨ Global variables 13 ⟩ +≡
param_stack: ↑pointer; { token list pointers for parameters }
param_ptr: 0 .. param_size; { first unused entry in param_stack }
max_param_stack: integer; { largest value of param_ptr, will be ≤ param_size + 9 }

```

**315.** The input routines must also interact with the processing of `\halign` and `\valign`, since the appearance of tab marks and `\cr` in certain places is supposed to trigger the beginning of special  $\langle v_j \rangle$  template text in the scanner. This magic is accomplished by an *align\_state* variable that is increased by 1 when a ‘{’ is scanned and decreased by 1 when a ‘}’ is scanned. The *align\_state* is nonzero during the  $\langle u_j \rangle$  template, after which it is set to zero; the  $\langle v_j \rangle$  template begins when a tab mark or `\cr` occurs at a time that *align\_state* = 0.

```

⟨ Global variables 13 ⟩ +≡
align_state: integer; { group level with respect to current alignment }

```

**316.** Thus, the “current input state” can be very complicated indeed; there can be many levels and each level can arise in a variety of ways. The *show\_context* procedure, which is used by T<sub>E</sub>X’s error-reporting routine to print out the current input state on all levels down to the most recent line of characters from an input file, illustrates most of these conventions. The global variable *base\_ptr* contains the lowest level that was displayed by this procedure.

```

⟨ Global variables 13 ⟩ +≡
base_ptr: 0 .. stack_size; { shallowest level shown by show_context }

```

**317.** The status at each level is indicated by printing two lines, where the first line indicates what was read so far and the second line shows what remains to be read. The context is cropped, if necessary, so that the first line contains at most *half\_error\_line* characters, and the second contains at most *error\_line*. Non-current input levels whose *token\_type* is ‘*backed-up*’ are shown only if they have not been fully read.

```

procedure show_context; { prints where the scanner is }
  label done, done1;
  var old_setting: 0 .. max_selector; { saved selector setting }
      s: pointer; { temporary pointer }
      nn: integer; { number of contexts shown so far, less one }
      bottom_line: boolean; { have we reached the final context to be shown? }
  <Local variables for formatting calculations 321>
  begin base_ptr ← input_ptr; input_stack[base_ptr] ← cur_input; { store current state }
  nn ← -1; bottom_line ← false;
  loop begin cur_input ← input_stack[base_ptr]; { enter into the context }
    if (state ≠ token_list) then
      if (name > 17) ∨ (base_ptr = 0) then bottom_line ← true;
      if (base_ptr = input_ptr) ∨ bottom_line ∨ (nn < error_context_lines) then
        <Display the current context 318>
      else if nn = error_context_lines then
        begin print_nl("..."); incr(nn); { omitted if error_context_lines < 0 }
        end;
      if bottom_line then goto done;
      decr(base_ptr);
    end;
  done: cur_input ← input_stack[input_ptr]; { restore original state }
  end;

```

```

318. <Display the current context 318> ≡
  begin if (base_ptr = input_ptr) ∨ (state ≠ token_list) ∨ (token_type ≠ backed-up) ∨ (loc ≠ null) then
    { we omit backed-up token lists that have already been read }
    begin tally ← 0; { get ready to count characters }
    old_setting ← selector;
    if state ≠ token_list then
      begin <Print location of current line 319>;
      <Pseudoprint the line 324>;
      end
    else begin <Print type of token list 320>;
      <Pseudoprint the token list 325>;
      end;
    selector ← old_setting; { stop pseudoprinting }
    <Print two lines using the tricky pseudoprinted information 323>;
    incr(nn);
  end;
end

```

This code is used in section 317.

**319.** This routine should be changed, if necessary, to give the best possible indication of where the current line resides in the input file. For example, on some systems it is best to print both a page and line number.

```

⟨Print location of current line 319⟩ ≡
  if name ≤ 17 then
    if terminal_input then
      if base_ptr = 0 then print_nl("<*>")
      else print_nl("<insert>␣")
    else begin print_nl("<read>␣");
      if name = 17 then print_char("*") else print_int(name - 1);
      print_char(">");
    end
  else begin print_nl("1."); print_int(line);
  end;
  print_char("␣")

```

This code is used in section 318.

```

320. ⟨Print type of token list 320⟩ ≡
  case token_type of
    parameter: print_nl("<argument>␣");
    u_template, v_template: print_nl("<template>␣");
    backed_up: if loc = null then print_nl("<recently␣read>␣")
      else print_nl("<to␣be␣read␣again>␣");
    inserted: print_nl("<inserted␣text>␣");
    macro: begin print_ln; print_cs(name);
    end;
    output_text: print_nl("<output>␣");
    every_par_text: print_nl("<everypar>␣");
    every_math_text: print_nl("<everymath>␣");
    every_display_text: print_nl("<everydisplay>␣");
    every_hbox_text: print_nl("<everyhbox>␣");
    every_vbox_text: print_nl("<everyvbox>␣");
    every_job_text: print_nl("<everyjob>␣");
    every_cr_text: print_nl("<everycr>␣");
    mark_text: print_nl("<mark>␣");
    write_text: print_nl("<write>␣");
    othercases print_nl("?") { this should never happen }
  endcases

```

This code is used in section 318.

**321.** Here it is necessary to explain a little trick. We don't want to store a long string that corresponds to a token list, because that string might take up lots of memory; and we are printing during a time when an error message is being given, so we dare not do anything that might overflow one of T<sub>E</sub>X's tables. So 'pseudoprinting' is the answer: We enter a mode of printing that stores characters into a buffer of length *error\_line*, where character  $k + 1$  is placed into *trick\_buf*[ $k \bmod \text{error\_line}$ ] if  $k < \text{trick\_count}$ , otherwise character  $k$  is dropped. Initially we set  $\text{tally} \leftarrow 0$  and  $\text{trick\_count} \leftarrow 1000000$ ; then when we reach the point where transition from line 1 to line 2 should occur, we set  $\text{first\_count} \leftarrow \text{tally}$  and  $\text{trick\_count} \leftarrow \max(\text{error\_line}, \text{tally} + 1 + \text{error\_line} - \text{half\_error\_line})$ . At the end of the pseudoprinting, the values of *first\_count*, *tally*, and *trick\_count* give us all the information we need to print the two lines, and all of the necessary text is in *trick\_buf*.

Namely, let  $l$  be the length of the descriptive information that appears on the first line. The length of the context information gathered for that line is  $k = \text{first\_count}$ , and the length of the context information gathered for line 2 is  $m = \min(\text{tally}, \text{trick\_count}) - k$ . If  $l + k \leq h$ , where  $h = \text{half\_error\_line}$ , we print *trick\_buf*[ $0 \dots k - 1$ ] after the descriptive information on line 1, and set  $n \leftarrow l + k$ ; here  $n$  is the length of line 1. If  $l + k > h$ , some cropping is necessary, so we set  $n \leftarrow h$  and print '...' followed by

$$\text{trick\_buf}[(l + k - h + 3) \dots k - 1],$$

where subscripts of *trick\_buf* are circular modulo *error\_line*. The second line consists of  $n$  spaces followed by *trick\_buf*[ $k \dots (k + m - 1)$ ], unless  $n + m > \text{error\_line}$ ; in the latter case, further cropping is done. This is easier to program than to explain.

```

⟨Local variables for formatting calculations 321⟩ ≡
i: 0 .. buf_size; { index into buffer }
j: 0 .. buf_size; { end of current line in buffer }
l: 0 .. half_error_line; { length of descriptive information on line 1 }
m: integer; { context information gathered for line 2 }
n: 0 .. error_line; { length of line 1 }
p: integer; { starting or ending place in trick_buf }
q: integer; { temporary index }

```

This code is used in section 317.

**322.** The following code sets up the print routines so that they will gather the desired information.

```

define begin_pseudoprint ≡
    begin l ← tally; tally ← 0; selector ← pseudo; kcode_pos ← 0; trick_count ← 1000000;
    end
define set_trick_count ≡
    begin first_count ← tally;
    if (first_count > 0) ∧ (trick_buf2[(first_count - 1) mod error_line] = 1) then incr(first_count);
    trick_count ← first_count + 1 + error_line - half_error_line;
    if trick_count < error_line then trick_count ← error_line;
    end

```

**323.** And the following code uses the information after it has been gathered.

```

⟨Print two lines using the tricky pseudoprinted information 323⟩ ≡
  if trick_count = 1000000 then set_trick_count; { set_trick_count must be performed }
  if tally < trick_count then m ← tally - first_count
  else m ← trick_count - first_count; { context on line 2 }
  if l + first_count ≤ half_error_line then
    begin p ← 0; n ← l + first_count;
    end
  else begin print("..."); p ← l + first_count - half_error_line + 3; n ← half_error_line;
    end;
  if trick_buf2[p mod error_line] = 2 then
    begin p ← p + 1; n ← n - 1;
    end;
  for q ← p to first_count - 1 do print_char(trick_buf[q mod error_line]);
  print_ln;
  for q ← 1 to n do print_char(" "); { print n spaces to begin line 2 }
  if m + n ≤ error_line then p ← first_count + m
  else p ← first_count + (error_line - n - 3);
  if trick_buf2[(p - 1) mod error_line] = 1 then p ← p - 1;
  for q ← first_count to p - 1 do print_char(trick_buf[q mod error_line]);
  if m + n > error_line then print("...")

```

This code is used in section 318.

**324.** But the trick is distracting us from our current goal, which is to understand the input state. So let's concentrate on the data structures that are being pseudoprinted as we finish up the *show\_context* procedure.

```

⟨Pseudoprint the line 324⟩ ≡
  begin_pseudoprint;
  if buffer[limit] = end_line_char then j ← limit
  else j ← limit + 1; { determine the effective end of the line }
  if j > 0 then
    for i ← start to j - 1 do
      begin if i = loc then set_trick_count;
      print(buffer[i]);
      end

```

This code is used in section 318.

```

325. ⟨Pseudoprint the token list 325⟩ ≡
  begin_pseudoprint;
  if token_type < macro then
    begin if (token_type = backed_up) ∧ (loc ≠ null) then
      begin if (link(start) = null) ∧ (check_kanji(info(start))) then { wchar_token }
        begin cur_input ← input_stack[base_ptr - 1]; s ← get_avail; info(s) ← Lo(info(loc));
          cur_input ← input_stack[base_ptr]; link(start) ← s; show_token_list(start, loc, 100000);
          free_avail(s); link(start) ← null; goto done1;
          end;
        end;
      show_token_list(start, loc, 100000);
      end
    else show_token_list(link(start), loc, 100000); { avoid reference count }
  done1:

```

This code is used in section 318.

**326.** Here is the missing piece of *show\_token\_list* that is activated when the token beginning line 2 is about to be shown:

```
⟨Do magic computation 326⟩ ≡  
  set_trick_count
```

This code is used in section 298.

**327. Maintaining the input stacks.** The following subroutines change the input status in commonly needed ways.

First comes *push\_input*, which stores the current state and creates a new level (having, initially, the same properties as the old).

```

define push_input ≡ { enter a new input level, save the old }
  begin if input_ptr > max_in_stack then
    begin max_in_stack ← input_ptr;
    if input_ptr = stack_size then overflow("input_stack_size", stack_size);
    end;
    input_stack[input_ptr] ← cur_input; { stack the record }
    incr(input_ptr);
  end

```

**328.** And of course what goes up must come down.

```

define pop_input ≡ { leave an input level, re-enter the old }
  begin decr(input_ptr); cur_input ← input_stack[input_ptr];
  end

```

**329.** Here is a procedure that starts a new level of token-list input, given a token list *p* and its type *t*. If *t* = *macro*, the calling routine should set *name* and *loc*.

```

define back_list(#) ≡ begin_token_list(#, backed_up) { backs up a simple token list }
define ins_list(#) ≡ begin_token_list(#, inserted) { inserts a simple token list }
procedure begin_token_list(p : pointer; t : quarterword);
  begin push_input; state ← token_list; start ← p; token_type ← t;
  if t ≥ macro then { the token list starts with a reference count }
    begin add_token_ref(p);
    if t = macro then param_start ← param_ptr
    else begin loc ← link(p);
      if tracing_macros > 1 then
        begin begin_diagnostic; print_nl("");
        case t of
          mark_text: print_esc("mark");
          write_text: print_esc("write");
          othercases print_cmd_chr(assign_toks, t - output_text + output_routine_loc)
          endcases;
          print("->"); token_show(p); end_diagnostic(false);
        end;
      end;
    end
  end
  else loc ← p;
  end;

```

**330.** When a token list has been fully scanned, the following computations should be done as we leave that level of input. The *token\_type* tends to be equal to either *backed\_up* or *inserted* about 2/3 of the time.

```

procedure end_token_list; { leave a token-list input level }
  begin if token_type ≥ backed_up then { token list to be deleted }
    begin if token_type ≤ inserted then flush_list(start)
    else begin delete_token_ref(start); { update reference count }
      if token_type = macro then { parameters must be flushed }
        while param_ptr > param_start do
          begin decr(param_ptr); flush_list(param_stack[param_ptr]);
          end;
        end;
    end;
  end
else if token_type = u_template then
  if align_state > 500000 then align_state ← 0
  else fatal_error("(interwoven_alignment_preambles_are_not_allowed)");
pop_input; check_interrupt;
end;

```

**331.** Sometimes T<sub>E</sub>X has read too far and wants to “unscan” what it has seen. The *back\_input* procedure takes care of this by putting the token just scanned back into the input stream, ready to be read again. This procedure can be used only if *cur\_tok* represents the token to be replaced. Some applications of T<sub>E</sub>X use this procedure a lot, so it has been slightly optimized for speed.

```

procedure back_input; { undoes one token of input }
  var p: pointer; { a token list of length one }
  begin while (state = token_list) ∧ (loc = null) ∧ (token_type ≠ v_template) do end_token_list;
    { conserve stack space }
    p ← get_avail; info(p) ← cur_tok;
    if cur_tok < right_brace_limit then
      if cur_tok < left_brace_limit then decr(align_state)
      else incr(align_state);
    push_input; state ← token_list; start ← p; token_type ← backed_up; loc ← p;
    { that was back_list(p), without procedure overhead }
  end;

```

```

332. ⟨ Insert token p into TEX’s input 332 ⟩ ≡
  begin t ← cur_tok; cur_tok ← p; back_input; cur_tok ← t;
  end

```

This code is used in section 288.

**333.** The *back\_error* routine is used when we want to replace an offending token just before issuing an error message. This routine, like *back\_input*, requires that *cur\_tok* has been set. We disable interrupts during the call of *back\_input* so that the help message won’t be lost.

```

procedure back_error; { back up one token and call error }
  begin OK_to_interrupt ← false; back_input; OK_to_interrupt ← true; error;
  end;
procedure ins_error; { back up one inserted token and call error }
  begin OK_to_interrupt ← false; back_input; token_type ← inserted; OK_to_interrupt ← true; error;
  end;

```

**334.** The *begin\_file\_reading* procedure starts a new level of input for lines of characters to be read from a file, or as an insertion from the terminal. It does not take care of opening the file, nor does it set *loc* or *limit* or *line*.

```
procedure begin_file_reading;
  begin if in_open = max_in_open then overflow("text_input_levels", max_in_open);
  if first = buf_size then overflow("buffer_size", buf_size);
  incr(in_open); push_input; index ← in_open; source_filename_stack[index] ← 0;
  full_source_filename_stack[index] ← 0; line_stack[index] ← line; start ← first; state ← mid_line;
  name ← 0; { terminal_input is now true }
end;
```

**335.** Conversely, the variables must be downdated when such a level of input is finished:

```
procedure end_file_reading;
  begin first ← start; line ← line_stack[index];
  if name > 17 then a_close(cur_file); { forget it }
  pop_input; decr(in_open);
end;
```

**336.** In order to keep the stack from overflowing during a long sequence of inserted ‘\show’ commands, the following routine removes completed error-inserted lines from memory.

```
procedure clear_for_error_prompt;
  begin while (state ≠ token_list) ∧ terminal_input ∧ (input_ptr > 0) ∧ (loc > limit) do end_file_reading;
  print_ln; clear_terminal;
end;
```

**337.** To get TEX’s whole input mechanism going, we perform the following actions.

```
⟨ Initialize the input routines 337 ⟩ ≡
  begin input_ptr ← 0; max_in_stack ← 0; source_filename_stack[0] ← 0;
  full_source_filename_stack[0] ← 0; in_open ← 0; open_parens ← 0; max_buf_stack ← 0; param_ptr ← 0;
  max_param_stack ← 0; first ← buf_size;
  repeat buffer[first] ← 0; decr(first);
  until first = 0;
  scanner_status ← normal; warning_index ← null; first ← 1; state ← new_line; start ← 1; index ← 0;
  line ← 0; name ← 0; force_eof ← false; align_state ← 1000000;
  if ¬init_terminal then goto final_end;
  limit ← last; first ← last + 1; { init_terminal has set loc and last }
end
```

This code is used in section 1350.

**338. Getting the next token.** The heart of T<sub>E</sub>X's input mechanism is the *get\_next* procedure, which we shall develop in the next few sections of the program. Perhaps we shouldn't actually call it the "heart," however, because it really acts as T<sub>E</sub>X's eyes and mouth, reading the source files and gobbling them up. And it also helps T<sub>E</sub>X to regurgitate stored token lists that are to be processed again.

The main duty of *get\_next* is to input one token and to set *cur\_cmd* and *cur\_chr* to that token's command code and modifier. Furthermore, if the input token is a control sequence, the *eqtb* location of that control sequence is stored in *cur\_cs*; otherwise *cur\_cs* is set to zero.

Underlying this simple description is a certain amount of complexity because of all the cases that need to be handled. However, the inner loop of *get\_next* is reasonably short and fast.

When *get\_next* is asked to get the next token of a `\read` line, it sets *cur\_cmd* = *cur\_chr* = *cur\_cs* = 0 in the case that no more tokens appear on that line. (There might not be any tokens at all, if the *end\_line\_char* has *ignore* as its catcode.)

**339.** The value of *par\_loc* is the *eqtb* address of `\par`. This quantity is needed because a blank line of input is supposed to be exactly equivalent to the appearance of `\par`; we must set *cur\_cs* ← *par\_loc* when detecting a blank line.

```

⟨Global variables 13⟩ +≡
par_loc: pointer; { location of '\par' in eqtb }
par_token: halfword; { token representing '\par' }

```

**340.** ⟨Put each of T<sub>E</sub>X's primitives into the hash table 232⟩ +≡  
*primitive*("par", *par\_end*, 256); { cf. *scan\_file\_name* }  
*par\_loc* ← *cur\_val*; *par\_token* ← *cs\_token\_flag* + *par\_loc*;

**341.** ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +≡  
*par\_end*: *print\_esc*("par");

**342.** Before getting into *get\_next*, let's consider the subroutine that is called when an `\outer` control sequence has been scanned or when the end of a file has been reached. These two cases are distinguished by *cur\_cs*, which is zero at the end of a file.

**procedure** *check\_outer\_validity*;

```

var p: pointer; { points to inserted token list }
    q: pointer; { auxiliary pointer }
begin if scanner_status ≠ normal then

        { prepare to read the control sequence again }
      end;
      cur_cmd ← spacer; cur_chr ← " "; { replace it by a space }
    end

```

This code is used in section 342.

```

344. ⟨Tell the user what has run away and try to recover 344⟩ ≡
  begin runaway; { print a definition, argument, or preamble }
  if cur_cs = 0 then print_err("File ended")
  else begin cur_cs ← 0; print_err("Forbidden control sequence found");
    end;
  ⟨Print either 'definition' or 'use' or 'preamble' or 'text', and insert tokens that should lead to
    recovery 345⟩;
  print(" of "); sprint_cs(warning_index);
  help4("I suspect you have forgotten a `}' , causing me")
  ("to read past where you wanted me to stop.")
  ("I'll try to recover; but if the error is serious,")
  ("you'd better type `E' or `X' now and fix your file.");
  error;
  end

```

This code is used in section 342.

**345.** The recovery procedure can't be fully understood without knowing more about the TEX routines that should be aborted, but we can sketch the ideas here: For a runaway definition we will insert a right brace; for a runaway preamble, we will insert a special `\cr` token and a right brace; and for a runaway argument, we will set `long_state` to `outer_call` and insert `\par`.

```

⟨Print either 'definition' or 'use' or 'preamble' or 'text', and insert tokens that should lead to
  recovery 345⟩ ≡
  p ← get_avail;
  case scanner_status of
  defining: begin print(" while scanning definition"); info(p) ← right_brace_token + "}";
    end;
  matching: begin print(" while scanning use"); info(p) ← par_token; long_state ← outer_call;
    end;
  aligning: begin print(" while scanning preamble"); info(p) ← right_brace_token + "}"; q ← p;
    p ← get_avail; link(p) ← q; info(p) ← cs_token_flag + frozen_cr; align_state ← -1000000;
    end;
  absorbing: begin print(" while scanning text"); info(p) ← right_brace_token + "}";
    end;
  end; { there are no other cases }
  ins_list(p)

```

This code is used in section 344.

**346.** We need to mention a procedure here that may be called by `get_next`.

```

procedure firm_up_the_line; forward;

```

**347.** Now we're ready to take the plunge into *get\_next* itself. Parts of this routine are executed more often than any other instructions of T<sub>E</sub>X.

```

define switch = 25 { a label in get_next }
define start_cs = 26 { another }

procedure get_next; { sets cur_cmd, cur_chr, cur_cs to next token }
label restart, { go here to get the next input token }
    switch, { go here to eat the next character from a file }
    reswitch, { go here to digest it again }
    start_cs, { go here to start looking for a control sequence }
    found, { go here when a control sequence has been found }
    exit; { go here when the next input token has been got }
var k: 0 .. buf_size; { an index into buffer }
    t: halfword; { a token }
    cat: escape .. max_char_code; { cat_code(cur_chr), usually }
    l: 0 .. buf_size; { temporary index into buffer }
    c, cc: ASCII_code; { constituents of a possible expanded code }
    d: 2 .. 3; { number of excess characters in an expanded code }
begin restart: cur_cs ← 0;
if state ≠ token_list then ⟨Input from external file, goto restart if no input found 349⟩
else ⟨Input from token list, goto restart if end of list or if a parameter needs to be expanded 365⟩;
    ⟨If an alignment entry has just ended, take appropriate action 348⟩;
exit: end;

```

**348.** An alignment entry ends when a tab or \cr occurs, provided that the current level of braces is the same as the level that was present at the beginning of that alignment entry; i.e., provided that *align\_state* has returned to the value it had after the  $\langle u_j \rangle$  template for that entry.

⟨If an alignment entry has just ended, take appropriate action 348⟩ ≡

```

if cur_cmd ≤ car_ret then
    if cur_cmd ≥ tab_mark then
        if align_state = 0 then ⟨Insert the  $\langle v_j \rangle$  template and goto restart 800⟩

```

This code is used in section 347.

**349.** ⟨Input from external file, **goto** *restart* if no input found 349⟩ ≡

```

begin switch: if loc ≤ limit then { current line not yet finished }
    begin cur_chr ← buffer[loc]; incr(loc);
    if multistrlen(ustringcast(buffer), limit + 1, loc - 1) = 2 then
        begin cur_chr ← fromBUFF(ustringcast(buffer), limit + 1, loc - 1);
        cur_cmd ← kcat_code(kcatcodekey(cur_chr)); incr(loc);
        end
    else reswitch: cur_cmd ← cat_code(cur_chr);
    ⟨Change state if necessary, and goto switch if the current character should be ignored, or goto
    reswitch if the current character changes to another 350⟩;
    end
else begin state ← new_line;
    ⟨Move to next line of file, or goto restart if there is no next line, or return if a \read line has
    finished 368⟩;
    check_interrupt; goto switch;
    end;
end

```

This code is used in section 347.

**350.** The following 48-way switch accomplishes the scanning quickly, assuming that a decent Pascal compiler has translated the code. Note that the numeric values for *mid\_line*, *skip\_blanks*, and *new\_line* are spaced apart from each other by *max\_char\_code* + 1, so we can add a character's command code to the state to get a single number that characterizes both.

```

define any_state_plus(#)  $\equiv$  mid_line + #, mid_kanji + #, skip_blanks + #, new_line + #
⟨ Change state if necessary, and goto switch if the current character should be ignored, or goto reswitch if
  the current character changes to another 350 ⟩  $\equiv$ 
case state + cur_cmd of
  ⟨ Cases where character is ignored 351 ⟩: goto switch;
  any_state_plus(escape): ⟨ Scan a control sequence and set state  $\leftarrow$  skip_blanks or mid_line 362 ⟩;
  any_state_plus(active_char): ⟨ Process an active-character control sequence and set state  $\leftarrow$  mid_line 361 ⟩;
  any_state_plus(sup_mark): ⟨ If this sup_mark starts an expanded character like  $\hat{\wedge}$ A or  $\hat{\wedge}$ df, then goto
    reswitch, otherwise set state  $\leftarrow$  mid_line 360 ⟩;
  any_state_plus(invalid_char): ⟨ Decry the invalid character and goto restart 352 ⟩;
  ⟨ Handle situations involving spaces, braces, changes of state 353 ⟩
othercases do_nothing
endcases

```

This code is used in section 349.

```

351. ⟨ Cases where character is ignored 351 ⟩  $\equiv$ 
  any_state_plus(ignore), skip_blanks + spacer, new_line + spacer

```

This code is used in section 350.

**352.** We go to *restart* instead of to *switch*, because *state* might equal *token\_list* after the error has been dealt with (cf. *clear\_for\_error\_prompt*).

```

⟨ Decry the invalid character and goto restart 352 ⟩  $\equiv$

all_jcode(skip_blanks), all_jcode(new_line), all_jcode(mid_line): state  $\leftarrow$  mid_kanji;

```

This code is used in section 350.

**354.** ⟨Global variables 13⟩  $+\equiv$

`skip_mode: boolean;`

**355.** ⟨Set initial values of key variables 21⟩  $+\equiv$

`skip_mode  $\leftarrow$  true;`

**356.** When a character of type *spacer* gets through, its character code is changed to "`␣`" = `'40`. This means that the ASCII codes for tab and space, and for the space inserted at the end of a line, will be treated alike when macro parameters are being matched. We do this since such characters are indistinguishable on most computer terminal displays.

```

⟨Finish line, emit a space 356⟩  $\equiv$ 
begin loc  $\leftarrow$  limit + 1; cur_cmd  $\leftarrow$  spacer; cur_chr  $\leftarrow$  "␣";
end

```

This code is used in sections 353 and 353.

**357.** The following code is performed only when `cur_cmd = spacer`.

```

⟨Enter skip_blanks state, emit a space 357⟩  $\equiv$ 
begin state  $\leftarrow$  skip_blanks; cur_chr  $\leftarrow$  "␣";
end

```

This code is used in section 353.

**358.** ⟨Finish line, **goto** switch 358⟩  $\equiv$

```

begin loc  $\leftarrow$  limit + 1; goto switch;
end

```

This code is used in sections 353 and 353.

**359.** ⟨Finish line, emit a `\par` 359⟩  $\equiv$

```

begin loc  $\leftarrow$  limit + 1; cur_cs  $\leftarrow$  par_loc; cur_cmd  $\leftarrow$  eq_type(cur_cs); cur_chr  $\leftarrow$  equiv(cur_cs);
if cur_cmd  $\geq$  outer_call then check_outer_validity;
end

```

This code is used in section 353.

**360.** Notice that a code like  $\text{\textasciix8}$  becomes  $\text{\textasciix}$  if not followed by a hex digit.

```

define is_hex(#)  $\equiv ((\# \geq "0") \wedge (\# \leq "9")) \vee ((\# \geq "a") \wedge (\# \leq "f"))$ 
define hex_to_cur_chr  $\equiv$ 
    if  $c \leq "9"$  then  $cur\_chr \leftarrow c - "0"$  else  $cur\_chr \leftarrow c - "a" + 10$ ;
    if  $cc \leq "9"$  then  $cur\_chr \leftarrow 16 * cur\_chr + cc - "0"$ 
    else  $cur\_chr \leftarrow 16 * cur\_chr + cc - "a" + 10$ 

```

$\langle$ If this *sup\_mark* starts an expanded character like  $\text{\textasciixA}$  or  $\text{\textasciixdf}$ , then **goto** *reswitch*, otherwise set  $state \leftarrow mid\_line$  360  $\rangle \equiv$

```

begin if  $cur\_chr = buffer[loc]$  then
    if  $loc < limit$  then
        begin  $c \leftarrow buffer[loc + 1]$ ; if  $c < '200$  then { yes we have an expanded char }
            begin  $loc \leftarrow loc + 2$ ;
            if is_hex( $c$ ) then
                if  $loc \leq limit$  then
                    begin  $cc \leftarrow buffer[loc]$ ; if is_hex( $cc$ ) then
                        begin  $incr(loc)$ ; hex_to_cur_chr; goto reswitch;

                if  $c < '100$  then  $cur\_chr \leftarrow c + '100$  else  $cur\_chr \leftarrow c - '100$ ;
                goto reswitch;
            end;
        end;
     $state \leftarrow mid\_line$ ;
end

```

This code is used in section 350.

**361.**  $\langle$ Process an active-character control sequence and set  $state \leftarrow mid\_line$  361  $\rangle \equiv$

```

begin  $cur\_cs \leftarrow cur\_chr + active\_base$ ;  $cur\_cmd \leftarrow eq\_type(cur\_cs)$ ;  $cur\_chr \leftarrow equiv(cur\_cs)$ ;
 $state \leftarrow mid\_line$ ;
if  $cur\_cmd \geq outer\_call$  then check_outer_validity;
end

```

This code is used in section 350.

**362.** Control sequence names are scanned only when they appear in some line of a file; once they have been scanned the first time, their *eqtb* location serves as a unique identification, so T<sub>E</sub>X doesn't need to refer to the original name any more except when it prints the equivalent in symbolic form.

The program that scans a control sequence has been written carefully in order to avoid the blowups that might otherwise occur if a malicious user tried something like '\catcode`15=0'. The algorithm might look at *buffer*[*limit* + 1], but it never looks at *buffer*[*limit* + 2].

If expanded characters like '^A' or '^df' appear in or just following a control sequence name, they are converted to single characters in the buffer and the process is repeated, slowly but surely.

```

⟨Scan a control sequence and set state ← skip_blanks or mid_line 362⟩ ≡
  begin if loc > limit then cur_cs ← null_cs { state is irrelevant in this case }
  else begin k ← loc; cur_chr ← buffer[k]; incr(k);
    if multistrlen(ustringcast(buffer), limit + 1, k - 1) = 2 then

  end
  else fatal_error("***_(job_aborted,_no_legal_end_found)");
    {nonstop mode, which is intended for overnight batch processing, never waits for on-line input}
  end

```

This code is used in section 349.

**369.** The global variable *force\_eof* is normally *false*; it is set *true* by an **\endinput** command.

⟨Global variables 13⟩ +≡

*force\_eof*: *boolean*; {should the next **\input** be aborted early?}

**370.** ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 370⟩ ≡

```

begin incr(line); first ← start;
if ¬force_eof then
  begin if input_ln(cur_file, true) then {not end of file}
    firm_up_the_line {this sets limit}
  else force_eof ← true;
  end;
if force_eof then
  begin print_char(""); decr(open_parens); update_terminal; {show user that file has been read}
  force_eof ← false; end_file_reading; {resume previous level}
  check_outer_validity; goto restart;
  end;
if end_line_char_inactive then decr(limit)
else buffer[limit] ← end_line_char;
  first ← limit + 1; loc ← start; {ready to read}
end

```

This code is used in section 368.

**371.** If the user has set the *pausing* parameter to some positive value, and if nonstop mode has not been selected, each line of input is displayed on the terminal and the transcript file, followed by ‘=>’. T<sub>E</sub>X waits for a response. If the response is simply *carriage\_return*, the line is accepted as it stands, otherwise the line typed is used instead of the line in the file.

```

procedure firm_up_the_line;
  var k: 0 .. buf_size; { an index into buffer }
  begin limit ← last;
  if pausing > 0 then
    if interaction > nonstop_mode then
      begin wake_up_terminal; print_ln;
      if start < limit then
        for k ← start to limit - 1 do print(buffer[k]);
        first ← limit; prompt_input("=>"); { wait for user response }
        if last > first then
          begin for k ← first to last - 1 do { move line down in buffer }
            buffer[k + start - first] ← buffer[k];
          limit ← start + last - first;
          end;
        end;
      end;
    end;
  end;

```

**372.** Since *get\_next* is used so frequently in T<sub>E</sub>X, it is convenient to define three related procedures that do a little more:

*get\_token* not only sets *cur\_cmd* and *cur\_chr*, it also sets *cur\_tok*, a packed halfword version of the current token.

*get\_x\_token*, meaning “get an expanded token,” is like *get\_token*, but if the current token turns out to be a user-defined control sequence (i.e., a macro call), or a conditional, or something like *\topmark* or *\expandafter* or *\csname*, it is eliminated from the input by beginning the expansion of the macro or the evaluation of the conditional.

*x\_token* is like *get\_x\_token* except that it assumes that *get\_next* has already been called.

In fact, these three procedures account for almost every use of *get\_next*.

**373.** No new control sequences will be defined except during a call of *get\_token*, or when *\csname* compresses a token list, because *no\_new\_control\_sequence* is always *true* at other times.

```

procedure get_token; { sets cur_cmd, cur_chr, cur_tok }
  begin no_new_control_sequence ← false; get_next; no_new_control_sequence ← true;
  if cur_cs = 0 then
    if (cur_cmd = kanji) ∨ (cur_cmd = kana) ∨ (cur_cmd = other_kchar) then { wchar_token }
      cur_tok ← cur_chr
    else cur_tok ← (cur_cmd * '400) + cur_chr
  else cur_tok ← cs_token_flag + cur_cs;
  end;

```

**374. Expanding the next token.** Only a dozen or so command codes  $> max\_command$  can possibly be returned by *get\_next*; in increasing order, they are *undefined\_cs*, *expand\_after*, *no\_expand*, *input*, *if\_test*, *fi\_or\_else*, *cs\_name*, *convert*, *the*, *top\_bot\_mark*, *call*, *long\_call*, *outer\_call*, *long\_outer\_call*, and *end\_template*.

**375.** Sometimes, recursive calls to the following *expand* routine may cause exhaustion of the run-time calling stack, resulting in forced execution stops by the operating system. To diminish the chance of this happening, a counter is used to keep track of the recursion depth, in conjunction with a constant called *expand\_depth*.

This does not catch all possible infinite recursion loops, just the ones that exhaust the application calling stack. The actual maximum value of *expand\_depth* is outside of our control, but the initial setting of 10000 should be enough to prevent problems.

```
⟨Global variables 13⟩ +=
expand_depth_count: integer;
```

**376.** ⟨Set initial values of key variables 21⟩ +=  
*expand\_depth\_count* ← 0;

**377.** The *expand* subroutine is used when *cur\_cmd*  $> max\_command$ . It removes a “call” or a conditional or one of the other special operations just listed. It follows that *expand* might invoke itself recursively. In all cases, *expand* destroys the current token, but it sets things up so that the next *get\_next* will deliver the appropriate next token. The value of *cur\_tok* need not be known when *expand* is called.

Since several of the basic scanning routines communicate via global variables, their values are saved as local variables of *expand* so that recursive calls don’t invalidate them.

```
⟨Declare the procedure called macro_call 400⟩
⟨Declare the procedure called insert_relax 390⟩
procedure pass_text; forward;
procedure start_input; forward;
procedure conditional; forward;
procedure get_x_token; forward;
procedure conv_toks; forward;
procedure ins_the_toks; forward;
procedure expand;
  var t: halfword; { token that is being “expanded after” }
      p, q, r: pointer; { for list manipulation }
      j: 0 .. buf_size; { index into buffer }
      cv_backup: integer; { to save the global quantity cur_val }
      cvl_backup, radix_backup, co_backup: small_number; { to save cur_val_level, etc. }
      backup_backup: pointer; { to save link(backup_head) }
      save_scanner_status: small_number; { temporary storage of scanner_status }
  begin incr(expand_depth_count);
  if expand_depth_count ≥ expand_depth then overflow("expansion_depth", expand_depth);
  cv_backup ← cur_val; cvl_backup ← cur_val_level; radix_backup ← radix; co_backup ← cur_order;
  backup_backup ← link(backup_head);
  if cur_cmd < call then ⟨Expand a nonmacro 378⟩
  else if cur_cmd < end_template then macro_call
    else ⟨Insert a token containing frozen_endv 386⟩;
  cur_val ← cv_backup; cur_val_level ← cvl_backup; radix ← radix_backup; cur_order ← co_backup;
  link(backup_head) ← backup_backup; decr(expand_depth_count);
  end;
```

```

378.  ⟨Expand a nonmacro 378⟩ ≡
  begin if tracing_commands > 1 then show_cur_cmd_chr;
  case cur_cmd of
  top_bot_mark: ⟨Insert the appropriate mark text into the scanner 397⟩;
  expand_after: ⟨Expand the token after the next token 379⟩;
  no_expand: ⟨Suppress expansion of the next token 380⟩;
  cs_name: ⟨Manufacture a control sequence name 383⟩;
  convert: conv_toks; {this procedure is discussed in Part 27 below}
  the: ins_the_toks; {this procedure is discussed in Part 27 below}
  if_test: conditional; {this procedure is discussed in Part 28 below}
  fi_or_else: ⟨Terminate the current conditional and skip to \fi 521⟩;
  input: ⟨Initiate or terminate input from a file 389⟩;
  othercases ⟨Complain about an undefined macro 381⟩
  endcases;
  end

```

This code is used in section 377.

**379.** It takes only a little shuffling to do what TEX calls `\expandafter`.

```

⟨Expand the token after the next token 379⟩ ≡
  begin get_token; t ← cur_tok; get_token;
  if cur_cmd > max_command then expand else back_input;
  cur_tok ← t; back_input;
  end

```

This code is used in section 378.

**380.** The implementation of `\noexpand` is a bit trickier, because it is necessary to insert a special ‘*dont\_expand*’ marker into TEX’s reading mechanism. This special marker is processed by *get\_next*, but it does not slow down the inner loop.

Since `\outer` macros might arise here, we must also clear the *scanner\_status* temporarily.

```

⟨Suppress expansion of the next token 380⟩ ≡
  begin save_scanner_status ← scanner_status; scanner_status ← normal; get_token;
  scanner_status ← save_scanner_status; t ← cur_tok; back_input;
  {now start and loc point to the backed-up token t}
  if t ≥ cs_token_flag then
  begin p ← get_avail; info(p) ← cs_token_flag + frozen_dont_expand; link(p) ← loc; start ← p;
  loc ← p;
  end;
  end

```

This code is used in section 378.

```

381.  ⟨Complain about an undefined macro 381⟩ ≡
  begin print_err("Undefined_control_sequence");
  help5("The_control_sequence_at_the_end_of_the_top_line")
  ("of_your_error_message_was_never_defined.If_you_have")
  ("misspelled_it_(e.g.,`hobx`),_type_`I`_and_the_correct")
  ("spelling_(e.g.,_`I\hbox`)_Otherwise_just_continue,")
  ("and_I'll_forget_about_whatsoever_was_undefined."); error;
  end

```

This code is used in section 378.

**382.** The *expand* procedure and some other routines that construct token lists find it convenient to use the following macros, which are valid only if the variables *p* and *q* are reserved for token-list building.

```

define store_new_token(#) ≡
    begin q ← get_avail; link(p) ← q; info(q) ← #; p ← q; { link(p) is null }
    end
define fast_store_new_token(#) ≡
    begin fast_get_avail(q); link(p) ← q; info(q) ← #; p ← q; { link(p) is null }
    end

```

**383.** ⟨ Manufacture a control sequence name 383 ⟩ ≡

```

begin r ← get_avail; p ← r; { head of the list of characters }
repeat get_x_token;
    if cur_cs = 0 then store_new_token(cur_tok);
until cur_cs ≠ 0;
if cur_cmd ≠ end_cs_name then ⟨ Complain about missing \endcsname 384 ⟩;
⟨ Look up the characters of list r in the hash table, and set cur_cs 385 ⟩;
flush_list(r);
if eq_type(cur_cs) = undefined_cs then
    begin eq_define(cur_cs, relax, 256); { N.B.: The save_stack might change }
    end; { the control sequence will now match '\relax' }
cur_tok ← cur_cs + cs_token_flag; back_input;
end

```

This code is used in section 378.

**384.** ⟨ Complain about missing \endcsname 384 ⟩ ≡

```

begin print_err("Missing_"); print_esc("endcsname"); print("_inserted");
help2("The_control_sequence_marked_to_be_read_again_should")
("not_appear_between_\\csname_and_\\endcsname."); back_error;
end

```

This code is used in section 383.

**385.** ⟨ Look up the characters of list *r* in the hash table, and set *cur\_cs* 385 ⟩ ≡

```

j ← first; p ← link(r);
while p ≠ null do
    begin if j ≥ max_buf_stack then
        begin max_buf_stack ← j + 1;
        if max_buf_stack = buf_size then overflow("buffer_size", buf_size);
        end;
        if check_kanji(info(p)) then { wchar_token }
            begin buffer[j] ← Hi(info(p)); incr(j);
            end;
        buffer[j] ← Lo(info(p)); incr(j); p ← link(p);
        end;
    if j > first + 1 then
        begin no_new_control_sequence ← false; cur_cs ← id_lookup(first, j - first);
        no_new_control_sequence ← true;
        end
    else if j = first then cur_cs ← null_cs { the list is empty }
        else cur_cs ← single_base + buffer[first] { the list has length one }

```

This code is used in section 383.

**386.** An *end\_template* command is effectively changed to an *endv* command by the following code. (The reason for this is discussed below; the *frozen\_end\_template* at the end of the template has passed the *check\_outer\_validity* test, so its mission of error detection has been accomplished.)

```
⟨Insert a token containing frozen_endv 386⟩ ≡
  begin cur_tok ← cs_token_flag + frozen_endv; back_input;
  end
```

This code is used in section 377.

**387.** The processing of `\input` involves the *start\_input* subroutine, which will be declared later; the processing of `\endinput` is trivial.

```
⟨Put each of TEX's primitives into the hash table 232⟩ +≡
  primitive("input", input, 0);
  primitive("endinput", input, 1);
```

**388.** ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +≡  
*input*: **if** *chr\_code* = 0 **then** *print\_esc*("input") **else** *print\_esc*("endinput");

```
389. ⟨Initiate or terminate input from a file 389⟩ ≡
  if cur_chr > 0 then force_eof ← true
  else if name_in_progress then insert_relax
  else start_input
```

This code is used in section 378.

**390.** Sometimes the expansion looks too far ahead, so we want to insert a harmless `\relax` into the user's input.

```
⟨Declare the procedure called insert_relax 390⟩ ≡
procedure insert_relax;
  begin cur_tok ← cs_token_flag + cur_cs; back_input; cur_tok ← cs_token_flag + frozen_relax; back_input;
  token_type ← inserted;
  end;
```

This code is used in section 377.

**391.** Here is a recursive procedure that is T<sub>E</sub>X's usual way to get the next token of input. It has been slightly optimized to take account of common cases.

```
procedure get_x_token; { sets cur_cmd, cur_chr, cur_tok, and expands macros }
  label restart, done;
  begin restart: get_next;
  if cur_cmd ≤ max_command then goto done;
  if cur_cmd ≥ call then
    if cur_cmd < end_template then macro_call
    else begin cur_cs ← frozen_endv; cur_cmd ← endv; goto done; { cur_chr = null_list }
    end
  else expand;
  goto restart;
done: if cur_cs = 0 then
  if (cur_cmd = kanji) ∨ (cur_cmd = kana) ∨ (cur_cmd = other_kchar) then cur_tok ← cur_chr
  else cur_tok ← (cur_cmd * 400) + cur_chr
  else cur_tok ← cs_token_flag + cur_cs;
  end;
```

**392.** The *get\_x\_token* procedure is equivalent to two consecutive procedure calls: *get\_next*; *x\_token*.

```

procedure x_token; { get_x_token without the initial get_next }
  begin while cur_cmd > max_command do
    begin expand; get_next;
    end;
  if cur_cs = 0 then
    if (cur_cmd = kanji) ∨ (cur_cmd = kana) ∨ (cur_cmd = other_kchar) then cur_tok ← cur_chr
    else cur_tok ← (cur_cmd * '400) + cur_chr
  else cur_tok ← cs_token_flag + cur_cs;
  end;

```

**393.** A control sequence that has been \def'ed by the user is expanded by T<sub>E</sub>X's *macro\_call* procedure.

Before we get into the details of *macro\_call*, however, let's consider the treatment of primitives like \topmark, since they are essentially macros without parameters. The token lists for such marks are kept in a global array of five pointers; we refer to the individual entries of this array by symbolic names *top\_mark*, etc. The value of *top\_mark* is either *null* or a pointer to the reference count of a token list.

```

define top_mark_code = 0 { the mark in effect at the previous page break }
define first_mark_code = 1 { the first mark between top_mark and bot_mark }
define bot_mark_code = 2 { the mark in effect at the current page break }
define split_first_mark_code = 3 { the first mark found by \vsplit }
define split_bot_mark_code = 4 { the last mark found by \vsplit }
define top_mark ≡ cur_mark[top_mark_code]
define first_mark ≡ cur_mark[first_mark_code]
define bot_mark ≡ cur_mark[bot_mark_code]
define split_first_mark ≡ cur_mark[split_first_mark_code]
define split_bot_mark ≡ cur_mark[split_bot_mark_code]

```

⟨ Global variables 13 ⟩ +≡

```

cur_mark: array [top_mark_code .. split_bot_mark_code] of pointer; { token lists for marks }

```

**394.** ⟨ Set initial values of key variables 21 ⟩ +≡

```

top_mark ← null; first_mark ← null; bot_mark ← null; split_first_mark ← null; split_bot_mark ← null;

```

**395.** ⟨ Put each of T<sub>E</sub>X's primitives into the hash table 232 ⟩ +≡

```

primitive("topmark", top_bot_mark, top_mark_code);
primitive("firstmark", top_bot_mark, first_mark_code);
primitive("botmark", top_bot_mark, bot_mark_code);
primitive("splitfirstmark", top_bot_mark, split_first_mark_code);
primitive("splitbotmark", top_bot_mark, split_bot_mark_code);

```

**396.** ⟨ Cases of *print\_cmd\_chr* for symbolic printing of primitives 233 ⟩ +≡

```

top_bot_mark: case chr_code of
  first_mark_code: print_esc("firstmark");
  bot_mark_code: print_esc("botmark");
  split_first_mark_code: print_esc("splitfirstmark");
  split_bot_mark_code: print_esc("splitbotmark");
  othercases print_esc("topmark")
endcases;

```

**397.** The following code is activated when *cur\_cmd* = *top\_bot\_mark* and when *cur\_chr* is a code like *top\_mark\_code*.

```

⟨Insert the appropriate mark text into the scanner 397⟩ ≡
  begin if cur_mark[cur_chr] ≠ null then begin_token_list(cur_mark[cur_chr], mark_text);
  end

```

This code is used in section 378.

**398.** Now let's consider *macro\_call* itself, which is invoked when T<sub>E</sub>X is scanning a control sequence whose *cur\_cmd* is either *call*, *long\_call*, *outer\_call*, or *long\_outer\_call*. The control sequence definition appears in the token list whose reference count is in location *cur\_chr* of *mem*.

The global variable *long\_state* will be set to *call* or to *long\_call*, depending on whether or not the control sequence disallows **\par** in its parameters. The *get\_next* routine will set *long\_state* to *outer\_call* and emit **\par**, if a file ends or if an **\outer** control sequence occurs in the midst of an argument.

```

⟨Global variables 13⟩ +≡
long_state: call .. long_outer_call; { governs the acceptance of \par }

```

**399.** The parameters, if any, must be scanned before the macro is expanded. Parameters are token lists without reference counts. They are placed on an auxiliary stack called *pstack* while they are being scanned, since the *param\_stack* may be losing entries during the matching process. (Note that *param\_stack* can't be gaining entries, since *macro\_call* is the only routine that puts anything onto *param\_stack*, and it is not recursive.)

```

⟨Global variables 13⟩ +≡
pstack: array [0 .. 8] of pointer; { arguments supplied to a macro }

```

**400.** After parameter scanning is complete, the parameters are moved to the *param\_stack*. Then the macro body is fed to the scanner; in other words, *macro\_call* places the defined text of the control sequence at the top of T<sub>E</sub>X's input stack, so that *get\_next* will proceed to read it next.

The global variable *cur\_cs* contains the *eqtb* address of the control sequence being expanded, when *macro\_call* begins. If this control sequence has not been declared `\long`, i.e., if its command code in the *eq\_type* field is not *long\_call* or *long\_outer\_call*, its parameters are not allowed to contain the control sequence `\par`. If an illegal `\par` appears, the macro call is aborted, and the `\par` will be rescanned.

```

⟨Declare the procedure called macro_call 400⟩ ≡
procedure macro_call; { invokes a user-defined control sequence }
  label exit, continue, done, done1, found;
  var r: pointer; { current node in the macro's token list }
    p: pointer; { current node in parameter token list being built }
    q: pointer; { new node being put into the token list }
    s: pointer; { backup pointer for parameter matching }
    t: pointer; { cycle pointer for backup recovery }
    u, v: pointer; { auxiliary pointers for backup recovery }
    rbrace_ptr: pointer; { one step before the last right_brace token }
    n: small_number; { the number of parameters scanned }
    unbalance: halfword; { unmatched left braces in current parameter }
    m: halfword; { the number of tokens or groups (usually) }
    ref_count: pointer; { start of the token list }
    save_scanner_status: small_number; { scanner_status upon entry }
    save_warning_index: pointer; { warning_index upon entry }
    match_chr: ASCII_code; { character used in parameter }
  begin save_scanner_status ← scanner_status; save_warning_index ← warning_index;
  warning_index ← cur_cs; ref_count ← cur_chr; r ← link(ref_count); n ← 0;
  if tracing_macros > 0 then ⟨Show the text of the macro being expanded 412⟩;
  if info(r) ≠ end_match_token then ⟨Scan the parameters and make link(r) point to the macro body;
    but return if an illegal \par is detected 402⟩;
  ⟨Feed the macro body and its parameters to the scanner 401⟩;
  exit: scanner_status ← save_scanner_status; warning_index ← save_warning_index;
  end;

```

This code is used in section 377.

**401.** Before we put a new token list on the input stack, it is wise to clean off all token lists that have recently been depleted. Then a user macro that ends with a call to itself will not require unbounded stack space.

```

⟨Feed the macro body and its parameters to the scanner 401⟩ ≡
  while (state = token_list) ∧ (loc = null) ∧ (token_type ≠ v_template) do end_token_list;
    { conserve stack space }
  begin_token_list(ref_count, macro); name ← warning_index; loc ← link(r);
  if n > 0 then
    begin if param_ptr + n > max_param_stack then
      begin max_param_stack ← param_ptr + n;
      if max_param_stack > param_size then overflow("parameter_stack_size", param_size);
      end;
    for m ← 0 to n - 1 do param_stack[param_ptr + m] ← pstack[m];
    param_ptr ← param_ptr + n;
  end

```

This code is used in section 400.

**402.** At this point, the reader will find it advisable to review the explanation of token list format that was presented earlier, since many aspects of that format are of importance chiefly in the *macro\_call* routine.

The token list might begin with a string of compulsory tokens before the first *match* or *end\_match*. In that case the macro name is supposed to be followed by those tokens; the following program will set *s* = *null* to represent this restriction. Otherwise *s* will be set to the first token of a string that will delimit the next parameter.

```

⟨Scan the parameters and make link(r) point to the macro body; but return if an illegal \par is
detected 402⟩ ≡
begin scanner_status ← matching; unbalance ← 0; long_state ← eq_type(cur_cs);
if long_state ≥ outer_call then long_state ← long_state - 2;
repeat link(temp_head) ← null;
  if (info(r) > match_token + 255) ∨ (info(r) < match_token) then s ← null
  else begin match_chr ← info(r) - match_token; s ← link(r); r ← s; p ← temp_head; m ← 0;
  end;
  ⟨Scan a parameter until its delimiter string has been found; or, if s = null, simply scan the delimiter
  string 403⟩;
  { now info(r) is a token whose command code is either match or end_match }
until info(r) = end_match_token;
end

```

This code is used in section 400.

**403.** If *info(r)* is a *match* or *end\_match* command, it cannot be equal to any token found by *get\_token*. Therefore an undelimited parameter—i.e., a *match* that is immediately followed by *match* or *end\_match*—will always fail the test '*cur\_tok* = *info(r)*' in the following algorithm.

```

⟨Scan a parameter until its delimiter string has been found; or, if s = null, simply scan the delimiter
string 403⟩ ≡
continue: get_token; { set cur_tok to the next token of input }
if cur_tok = info(r) then ⟨Advance r; goto found if the parameter delimiter has been fully matched,
otherwise goto continue 405⟩;
⟨Contribute the recently matched tokens to the current parameter, and goto continue if a partial match
is still in effect; but abort if s = null 408⟩;
if cur_tok = par_token then
  if long_state ≠ long_call then ⟨Report a runaway argument and abort 407⟩;
if cur_tok < right_brace_limit then
  if cur_tok < left_brace_limit then ⟨Contribute an entire group to the current parameter 410⟩
  else ⟨Report an extra right brace and goto continue 406⟩
else ⟨Store the current token, but goto continue if it is a blank space that would become an undelimited
parameter 404⟩;
  incr(m);
  if info(r) > end_match_token then goto continue;
  if info(r) < match_token then goto continue;
found: if s ≠ null then ⟨Tidy up the parameter just scanned, and tuck it away 411⟩

```

This code is used in section 402.

**404.** ⟨Store the current token, but **goto** *continue* if it is a blank space that would become an undelimited parameter 404⟩ ≡

```
begin if cur_tok = space_token then
  if info(r) ≤ end_match_token then
    if info(r) ≥ match_token then goto continue;
  store_new_token(cur_tok);
end
```

This code is used in section 403.

**405.** A slightly subtle point arises here: When the parameter delimiter ends with ‘#{’, the token list will have a left brace both before and after the *end\_match*. Only one of these should affect the *align\_state*, but both will be scanned, so we must make a correction.

⟨Advance *r*; **goto** *found* if the parameter delimiter has been fully matched, otherwise **goto** *continue* 405⟩ ≡

```
begin r ← link(r);
  if (info(r) ≥ match_token) ∧ (info(r) ≤ end_match_token) then

  for m ← 0 to n do flush_list(pstack[m]);
  return;
end
```

This code is used in sections 403 and 410.

**408.** When the following code becomes active, we have matched tokens from  $s$  to the predecessor of  $r$ , and we have found that  $cur\_tok \neq info(r)$ . An interesting situation now presents itself: If the parameter is to be delimited by a string such as ‘ab’, and if we have scanned ‘aa’, we want to contribute one ‘a’ to the current parameter and resume looking for a ‘b’. The program must account for such partial matches and for others that can be quite complex. But most of the time we have  $s = r$  and nothing needs to be done.

Incidentally, it is possible for `\par` tokens to sneak in to certain parameters of non-`\long` macros. For example, consider a case like ‘`\def\aa#1\par!{...}`’ where the first `\par` is not followed by an exclamation point. In such situations it does not seem appropriate to prohibit the `\par`, so TEX keeps quiet about this bending of the rules.

```

⟨Contribute the recently matched tokens to the current parameter, and goto continue if a partial match is
still in effect; but abort if  $s = null$  408⟩ ≡

  end_diagnostic(false);
end

```

This code is used in section 400.

**413. Basic scanning subroutines.** Let's turn now to some procedures that TEX calls upon frequently to digest certain kinds of patterns in the input. Most of these are quite simple; some are quite elaborate. Almost all of the routines call *get\_x\_token*, which can cause them to be invoked recursively.

**414.** The *scan\_left\_brace* routine is called when a left brace is supposed to be the next non-blank token. (The term "left brace" means, more precisely, a character whose catcode is *left\_brace*.) TEX allows `\relax` to appear before the *left\_brace*.

```

procedure scan_left_brace; { reads a mandatory left_brace }
  begin ⟨ Get the next non-blank non-relax non-call token 415 ⟩;
  if cur_cmd ≠ left_brace then
    begin print_err("Missing_{inserted}");
    help4 ("A_left_brace_was_mandatory_here,_so_I've_put_one_in.")
    ("You_might_want_to_delete_and/or_insert_some_corrections")
    ("so_that_I_will_find_a_matching_right_brace_soon.")
    ("(If_you're_confused_by_all_this,_try_typing`I`now.)"); back_error;
    cur_tok ← left_brace_token + "{"; cur_cmd ← left_brace; cur_chr ← "{"; incr(align_state);
    end;
  end;

```

**415.** ⟨ Get the next non-blank non-relax non-call token 415 ⟩ ≡  
**repeat** *get\_x\_token*;  
**until** (*cur\_cmd* ≠ *spacer*) ∧ (*cur\_cmd* ≠ *relax*)

This code is used in sections 414, 1090, 1096, 1163, 1172, 1223, 1238, and 1283.

**416.** The *scan\_optional\_equals* routine looks for an optional '=' sign preceded by optional spaces; '`\relax`' is not ignored here.

```

procedure scan_optional_equals;
  begin ⟨ Get the next non-blank non-call token 417 ⟩;
  if cur_tok ≠ other_token + "=" then back_input;
  end;

```

**417.** ⟨ Get the next non-blank non-call token 417 ⟩ ≡  
**repeat** *get\_x\_token*;  
**until** *cur\_cmd* ≠ *spacer*

This code is used in sections 416, 452, 466, 514, 537, 588, 796, 802, and 1057.

**418.** In case you are getting bored, here is a slightly less trivial routine: Given a string of lowercase letters, like ‘pt’ or ‘plus’ or ‘width’, the *scan\_keyword* routine checks to see whether the next tokens of input match this string. The match must be exact, except that uppercase letters will match their lowercase counterparts; uppercase equivalents are determined by subtracting “a” – “A”, rather than using the *uc\_code* table, since T<sub>E</sub>X uses this routine only for its own limited set of keywords.

If a match is found, the characters are effectively removed from the input and *true* is returned. Otherwise *false* is returned, and the input is left essentially unchanged (except for the fact that some macros may have been expanded, etc.).

```
function scan_keyword(s : str_number): boolean; { look for a given string }
  label exit;
  var p: pointer; { tail of the backup list }
      q: pointer; { new node being added to the token list via store_new_token }
      k: pool_pointer; { index into str_pool }
  begin p ← backup_head; link(p) ← null; k ← str_start[s];
  while k < str_start[s + 1] do
    begin get_x_token; { recursion is possible here }
    if (cur_cs = 0) ∧ ((cur_chr = so(str_pool[k])) ∨ (cur_chr = so(str_pool[k] – “a” + “A”))) then
      begin store_new_token(cur_tok); incr(k);
      end
    else if (cur_cmd ≠ spacer) ∨ (p ≠ backup_head) then
      begin back_input;
      if p ≠ backup_head then back_list(link(backup_head));
      scan_keyword ← false; return;
      end;
    end;
  flush_list(link(backup_head)); scan_keyword ← true;
exit: end;
```

**419.** Here is a procedure that sounds an alarm when mu and non-mu units are being switched.

```
procedure mu_error;
  begin print_err("Incompatible glue units");
  help1("I'm going to assume that 1mu=1pt when they're mixed."); error;
  end;
```

**420.** The next routine ‘*scan\_something\_internal*’ is used to fetch internal numeric quantities like ‘\hsize’, and also to handle the ‘\the’ when expanding constructions like ‘\the\toks0’ and ‘\the\baselineskip’. Soon we will be considering the *scan\_int* procedure, which calls *scan\_something\_internal*; on the other hand, *scan\_something\_internal* also calls *scan\_int*, for constructions like ‘\catcode\\$\\$’ or ‘\fontdimen 3 \ff’. So we have to declare *scan\_int* as a *forward* procedure. A few other procedures are also declared at this point.

```
procedure scan_int; forward; { scans an integer value }
⟨ Declare procedures that scan restricted classes of integers 444 ⟩
⟨ Declare procedures that scan font-related stuff 588 ⟩
```

**421.** T<sub>E</sub>X doesn't know exactly what to expect when *scan\_something\_internal* begins. For example, an integer or dimension or glue value could occur immediately after '\hskip'; and one can even say \the with respect to token lists in constructions like '\xdef\o{\the\output}'. On the other hand, only integers are allowed after a construction like '\count'. To handle the various possibilities, *scan\_something\_internal* has a *level* parameter, which tells the "highest" kind of quantity that *scan\_something\_internal* is allowed to produce. Six levels are distinguished, namely *int\_val*, *dimen\_val*, *glue\_val*, *mu\_val*, *ident\_val*, and *tok\_val*.

The output of *scan\_something\_internal* (and of the other routines *scan\_int*, *scan\_dimen*, and *scan\_glue* below) is put into the global variable *cur\_val*, and its level is put into *cur\_val\_level*. The highest values of *cur\_val\_level* are special: *mu\_val* is used only when *cur\_val* points to something in a "muskip" register, or to one of the three parameters \thinmuskip, \medmuskip, \thickmuskip; *ident\_val* is used only when *cur\_val* points to a font identifier; *tok\_val* is used only when *cur\_val* points to *null* or to the reference count of a token list. The last two cases are allowed only when *scan\_something\_internal* is called with *level* = *tok\_val*.

If the output is glue, *cur\_val* will point to a glue specification, and the reference count of that glue will have been updated to reflect this reference; if the output is a nonempty token list, *cur\_val* will point to its reference count, but in this case the count will not have been updated. Otherwise *cur\_val* will contain the integer or scaled value in question.

```

define int_val = 0 { integer values }
define dimen_val = 1 { dimension values }
define glue_val = 2 { glue specifications }
define mu_val = 3 { math glue specifications }
define ident_val = 4 { font identifier }
define tok_val = 5 { token lists }

```

⟨Global variables 13⟩ +=

```

cur_val: integer; { value returned by numeric scanners }
cur_val_level: int_val .. tok_val; { the "level" of this value }

```

**422.** The hash table is initialized with '\count', '\dimen', '\skip', and '\muskip' all having *register* as their command code; they are distinguished by the *chr\_code*, which is either *int\_val*, *dimen\_val*, *glue\_val*, or *mu\_val*.

⟨Put each of T<sub>E</sub>X's primitives into the hash table 232⟩ +=

```

primitive("count", register, int_val); primitive("dimen", register, dimen_val);
primitive("skip", register, glue_val); primitive("muskip", register, mu_val);

```

**423.** ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +=

```

register: if chr_code = int_val then print_esc("count")
else if chr_code = dimen_val then print_esc("dimen")
else if chr_code = glue_val then print_esc("skip")
else print_esc("muskip");

```

**424.** OK, we're ready for *scan\_something\_internal* itself. A second parameter, *negative*, is set *true* if the value that is found should be negated. It is assumed that *cur\_cmd* and *cur\_chr* represent the first token of the internal quantity to be scanned; an error will be signalled if *cur\_cmd* < *min\_internal* or *cur\_cmd* > *max\_internal*.

```

This code is used in section 424.

**435.** Here is where `\lastpenalty`, `\lastkern`, and `\lastskip` are implemented. The reference count for `\lastskip` will be updated later.

We also handle `\inputlineno` and `\badness` here, because they are legal in similar contexts. The macro `find_effective_tail_pTeX` sets `tx` to the last non-`disp_node` of the current list.

```

define find_effective_tail_pTeX ≡ tx ← tail;
  if ¬is_char_node(tx) then
    if type(tx) = disp_node then
      begin tx ← prev_node;
      if ¬is_char_node(tx) then
        if type(tx) = disp_node then { disp_node from a discretionary }
          begin tx ← head; q ← link(head);
          while q ≠ prev_node do
            begin if is_char_node(q) then tx ← q
              else if type(q) ≠ disp_node then tx ← q;
            end;
            q ← link(q);
          end;
        end
      end
    end

```

```

define find_effective_tail ≡ find_effective_tail_pTeX

```

〈Fetch an item in the current node, if appropriate 435〉 ≡

```

if cur_chr > glue_val then
  begin if cur_chr = input_line_no_code then cur_val ← line
    else cur_val ← last_badness; { cur_chr = badness_code }
    cur_val_level ← int_val;
  end
else begin if cur_chr = glue_val then cur_val ← zero_glue else cur_val ← 0;
  find_effective_tail; cur_val_level ← cur_chr;
  if ¬is_char_node(tx) ∧ (tx ≠ head) ∧ (mode ≠ 0) then
    case cur_chr of
      int_val: if type(tx) = penalty_node then cur_val ← penalty(tx);
      dimen_val: if type(tx) = kern_node then cur_val ← width(tx);
      glue_val: if type(tx) = glue_node then
        begin cur_val ← glue_ptr(tx);
          if subtype(tx) = mu_glue then cur_val_level ← mu_val;
        end;
      end { there are no other cases }
    else if (mode = vmode) ∧ (tx = head) then

  if level ≠ tok_val then scanned_result(0)(dimen_val)
  else scanned_result(0)(int_val);
  end

```

This code is used in section 424.

**440.** When a *glue\_val* changes to a *dimen\_val*, we use the width component of the glue; there is no need to decrease the reference count, since it has not yet been increased. When a *dimen\_val* changes to an *int\_val*, we use scaled points so that the value doesn't actually change. And when a *mu\_val* changes to a *glue\_val*, the value doesn't change either.

```

⟨Convert cur_val to a lower level 440⟩ ≡
  begin if cur_val_level = glue_val then cur_val ← width(cur_val)
  else if cur_val_level = mu_val then mu_error;
  decr(cur_val_level);
  end

```

This code is used in section 424.

**441.** If *cur\_val* points to a glue specification at this point, the reference count for the glue does not yet include the reference by *cur\_val*. If *negative* is *true*, *cur\_val\_level* is known to be  $\leq mu\_val$ .

```

⟨Fix the reference count, if any, and negate cur_val if negative 441⟩ ≡
  if negative then
  if cur_val_level ≥ glue_val then
  begin cur_val ← new_spec(cur_val); ⟨Negate all three glue components of cur_val 442⟩;
  end
  else negate(cur_val)
  else if (cur_val_level ≥ glue_val) ∧ (cur_val_level ≤ mu_val) then add_glue_ref(cur_val)

```

This code is used in section 424.

442.  $\langle$  Negate all three glue components of *cur\_val* 442  $\rangle \equiv$   
**begin** *negate*(*width*(*cur\_val*)); *negate*(*stretch*(*cur\_val*)); *negate*(*shrink*(*cur\_val*));  
**end**

This code is used in section 441.

443. Our next goal is to write the *scan\_int* procedure, which scans anything that T<sub>E</sub>X treats as an integer. But first we might as well look at some simple applications of *scan\_int* that have already been made inside of *scan\_something\_internal*.

444.  $\langle$  Declare procedures that scan restricted classes of integers 444  $\rangle \equiv$

```
procedure scan_eight_bit_int;  

begin scan_int;  

if (cur_val < 0)  $\vee$  (cur_val > 255) then  

  begin print_err("Bad_register_code");  

  help2("A_register_number_must_be_between_0_and_255.")  

  ("I_changed_this_one_to_zero."); int_error(cur_val); cur_val  $\leftarrow$  0;  

  end;  

end;
```

This code is used in section 420.

445.  $\langle$  Declare procedures that scan restricted classes of integers 444  $\rangle + \equiv$

```
procedure scan_char_num;  

begin scan_int;  

if  $\neg$ is_char_ascii(cur_val)  $\wedge$   $\neg$ is_char_kanji(cur_val) then  

  begin print_err("Bad_character_code");  

  help2("A_character_number_must_be_between_0_and_255_or_KANJI_code.")  

  ("I_changed_this_one_to_zero."); int_error(cur_val); cur_val  $\leftarrow$  0;  

  end;  

end;
```

446. While we're at it, we might as well deal with similar routines that will be needed later.

$\langle$  Declare procedures that scan restricted classes of integers 444  $\rangle + \equiv$

```
procedure scan_four_bit_int;  

begin scan_int;  

if (cur_val < 0)  $\vee$  (cur_val > 15) then  

  begin print_err("Bad_number");  

  help2("Since_I_expected_to_read_a_number_between_0_and_15,"  

  ("I_changed_this_one_to_zero."); int_error(cur_val); cur_val  $\leftarrow$  0;  

  end;  

end;
```

447.  $\langle$  Declare procedures that scan restricted classes of integers 444  $\rangle + \equiv$

```
procedure scan_fifteen_bit_int;  

begin scan_int;  

if (cur_val < 0)  $\vee$  (cur_val > '77777) then  

  begin print_err("Bad_mathchar"); help2("A_mathchar_number_must_be_between_0_and_32767.")  

  ("I_changed_this_one_to_zero."); int_error(cur_val); cur_val  $\leftarrow$  0;  

  end;  

end;
```

448.  $\langle$  Declare procedures that scan restricted classes of integers 444  $\rangle + \equiv$

```

procedure scan_twenty_seven_bit_int;
  begin scan_int;
  if (cur_val < 0)  $\vee$  (cur_val > '777777777') then
    begin print_err("Bad_delimiter_code");
    help2("A_numeric_delimiter_code_must_be_between_0_and_2^{27}-1.")
    ("I_changed_this_one_to_zero."); int_error(cur_val); cur_val  $\leftarrow$  0;
    end;
  end;

```

449. An integer number can be preceded by any number of spaces and '+' or '-' signs. Then comes either a decimal constant (i.e., radix 10), an octal constant (i.e., radix 8, preceded by ^), a hexadecimal constant (radix 16, preceded by #), an alphabetic constant (preceded by %), or an internal variable. After scanning is complete, *cur\_val* will contain the answer, which must be at most  $2^{31} - 1 = 2147483647$  in absolute value. The value of *radix* is set to 10, 8, or 16 in the cases of decimal, octal, or hexadecimal constants, otherwise *radix* is set to zero. An optional space follows a constant.

```

define octal_token = other_token + "^" { apostrophe, indicates an octal constant }
define hex_token = other_token + "#" { double quote, indicates a hex constant }
define alpha_token = other_token + "%" { reverse apostrophe, precedes alpha constants }
define point_token = other_token + "." { decimal point }
define continental_point_token = other_token + "," { decimal point, Eurostyle }

```

$\langle$  Global variables 13  $\rangle + \equiv$

```

radix: small_number; { scan_int sets this to 8, 10, 16, or zero }

```

450. We initialize the following global variables just in case *expand* comes into action before any of the basic scanning routines has assigned them a value.

$\langle$  Set initial values of key variables 21  $\rangle + \equiv$

```

cur_val  $\leftarrow$  0; cur_val_level  $\leftarrow$  int_val; radix  $\leftarrow$  0; cur_order  $\leftarrow$  normal;

```

451. The *scan\_int* routine is used also to scan the integer part of a fraction; for example, the '3' in '3.14159' will be found by *scan\_int*. The *scan\_dimen* routine assumes that *cur\_tok* = *point\_token* after the integer part of such a fraction has been scanned by *scan\_int*, and that the decimal point has been backed up to be scanned again.

```

procedure scan_int; { sets cur_val to an integer }
  label done;
  var negative: boolean; { should the answer be negated? }
  m: integer; {  $2^{31} \text{ div } radix$ , the threshold of danger }
  d: small_number; { the digit just scanned }
  vacuous: boolean; { have no digits appeared? }
  OK_so_far: boolean; { has an error message been issued? }
  begin radix  $\leftarrow$  0; OK_so_far  $\leftarrow$  true;
   $\langle$  Get the next non-blank non-sign token; set negative appropriately 452  $\rangle$ ;
  if cur_tok = alpha_token then  $\langle$  Scan an alphabetic character code into cur_val 453  $\rangle$ 
  else if (cur_cmd  $\geq$  min_internal)  $\wedge$  (cur_cmd  $\leq$  max_internal) then
    scan_something_internal(int_val, false)
  else  $\langle$  Scan a numeric constant 455  $\rangle$ ;
  if negative then negate(cur_val);
  end;

```

**452.**  $\langle$  Get the next non-blank non-sign token; set *negative* appropriately 452  $\rangle \equiv$   
*negative*  $\leftarrow$  *false*;  
**repeat**  $\langle$  Get the next non-blank non-call token 417  $\rangle$ ;  
  **if** *cur\_tok* = *other\_token* + "-" **then**  
    **begin** *negative*  $\leftarrow$   $\neg$ *negative*; *cur\_tok*  $\leftarrow$  *other\_token* + "+";  
    **end**;  
  **until** *cur\_tok*  $\neq$  *other\_token* + "+"

This code is used in sections 451, 459, and 472.

**453.** A space is ignored after an alphabetic character constant, so that such constants behave like numeric ones.

$\langle$  Scan an alphabetic character code into *cur\_val* 453  $\rangle \equiv$   
**begin** *get\_token*; { suppress macro expansion }  
**if** *cur\_tok* < *cs\_token\_flag* **then**

This code is used in section 455.

**458.** The *scan\_dimen* routine is similar to *scan\_int*, but it sets *cur\_val* to a *scaled* value, i.e., an integral number of sp. One of its main tasks is therefore to interpret the abbreviations for various kinds of units and to convert measurements to scaled points.

There are three parameters: *mu* is *true* if the finite units must be ‘mu’, while *mu* is *false* if ‘mu’ units are disallowed; *inf* is *true* if the infinite units ‘fil’, ‘fill’, ‘filll’ are permitted; and *shortcut* is *true* if *cur\_val* already contains an integer and only the units need to be considered.

The order of infinity that was found in the case of infinite glue is returned in the global variable *cur\_order*.

⟨Global variables 13⟩ +≡

*cur\_order*: *glue\_ord*; {order of infinity found by *scan\_dimen*}

**459.** Constructions like ‘-‘77 pt’ are legal dimensions, so *scan\_dimen* may begin with *scan\_int*. This explains why it is convenient to use *scan\_int* also for the integer part of a decimal fraction.

Several branches of *scan\_dimen* work with *cur\_val* as an integer and with an auxiliary fraction *f*, so that the actual quantity of interest is  $cur\_val + f/2^{16}$ . At the end of the routine, this “unpacked” representation is put into the single word *cur\_val*, which suddenly switches significance from *integer* to *scaled*.

**define** *attach\_fraction* = 88 {go here to pack *cur\_val* and *f* into *cur\_val*}

**define** *attach\_sign* = 89 {go here when *cur\_val* is correct except perhaps for sign>}

**define** *scan\_normal\_dimen* ≡ *scan\_dimen*(*false*, *false*, *false*)

**procedure** *scan\_dimen*(*mu*, *inf*, *shortcut* : *boolean*); {sets *cur\_val* to a dimension}

**label** *done*, *done1*, *done2*, *found*, *not\_found*, *attach\_fraction*, *attach\_sign*;

**var** *negative*: *boolean*; {should the answer be negated?}

*f*: *integer*; {numerator of a fraction whose denominator is  $2^{16}$ }

⟨Local variables for dimension calculations 461⟩

    if cur_val_level = mu_val then goto attach_sign;
    if cur_val_level ≠ int_val then mu_error;
    end
  else begin scan_something_internal(dimen_val, false);
    if cur_val_level = dimen_val then goto attach_sign;
  end

```

This code is used in section 459.

```

461.  ⟨Local variables for dimension calculations 461⟩ ≡
num, denom: 1 .. 65536; {conversion ratio for the scanned units}
k, kk: small_number; {number of digits in a decimal fraction}
p, q: pointer; {top of decimal digit stack}
v: scaled; {an internal dimension}
save_cur_val: integer; {temporary storage of cur_val}

```

See also section 1417.

This code is used in section 459.

**462.** The following code is executed when *scan\_something\_internal* was called asking for *mu\_val*, when we really wanted a “mudimen” instead of “muglue.”

```

⟨Coerce glue to a dimension 462⟩ ≡
  if cur_val_level ≥ glue_val then
    begin v ← width(cur_val); delete_glue_ref(cur_val); cur_val ← v;
    end

```

This code is used in sections 460 and 466.

**463.** When the following code is executed, we have *cur\_tok* = *point\_token*, but this token has been backed up using *back\_input*; we must first discard it.

It turns out that a decimal point all by itself is equivalent to ‘0.0’. Let’s hope people don’t use that fact.

```

⟨Scan decimal fraction 463⟩ ≡
  begin k ← 0; p ← null; get_token; {point_token is being re-scanned}
  loop begin get_x_token;
    if (cur_tok > zero_token + 9) ∨ (cur_tok < zero_token) then goto done1;
    if k < 17 then {digits for k ≥ 17 cannot affect the result}
      begin q ← get_avail; link(q) ← p; info(q) ← cur_tok - zero_token; p ← q; incr(k);
      end;
    end;
  done1: for kk ← k downto 1 do
    begin dig[kk - 1] ← info(p); q ← p; p ← link(p); free_avail(q);
    end;
  f ← round_decimals(k);
  if cur_cmd ≠ spacer then back_input;
  end

```

This code is used in section 459.

**464.** Now comes the harder part: At this point in the program, *cur\_val* is a nonnegative integer and  $f/2^{16}$  is a nonnegative fraction less than 1; we want to multiply the sum of these two quantities by the appropriate factor, based on the specified units, in order to produce a *scaled* result, and we want to do the calculation with fixed point arithmetic that does not overflow.

```

⟨Scan units and set cur_val to  $x \cdot (cur\_val + f/2^{16})$ , where there are x sp per unit; goto attach_sign if the
  units are internal 464) ≡
if inf then ⟨Scan for fil units; goto attach_fraction if found 465);
⟨Scan for units that are internal dimensions; goto attach_sign with cur_val set if found 466);
if mu then ⟨Scan for mu units and goto attach_fraction 467);
if scan_keyword("true") then ⟨Adjust for the magnification ratio 468);
if scan_keyword("pt") then goto attach_fraction; {the easy case}
⟨Scan for all other units and adjust cur_val and f accordingly; goto done in the case of scaled
  points 469);
attach_fraction: if cur_val ≥ 40000 then arith_error ← true
  else cur_val ← cur_val * unity + f;
done:

```

This code is used in section 459.

**465.** A specification like ‘fillllll’ or ‘fill L L L’ will lead to two error messages (one for each additional keyword “l”).

```

⟨Scan for fil units; goto attach_fraction if found 465) ≡
if scan_keyword("fil") then
  begin cur_order ← fil;
  while scan_keyword("l") do
    begin if cur_order = filll then
      begin print_err("Illegal unit of measure("); print("replaced by filll");

**472.** The final member of TEX's value-scanning trio is *scan\_glue*, which makes *cur\_val* point to a glue specification. The reference count of that glue spec will take account of the fact that *cur\_val* is pointing to it.

The *level* parameter should be either *glue\_val* or *mu\_val*.

Since *scan\_dimen* was so much more complex than *scan\_int*, we might expect *scan\_glue* to be even worse. But fortunately, it is very simple, since most of the work has already been done.

```

procedure scan_glue(level : small_number); { sets cur_val to a glue spec pointer }
  label exit;
  var negative: boolean; { should the answer be negated? }
      q: pointer; { new glue specification }
      mu: boolean; { does level = mu_val? }
  begin mu ← (level = mu_val); ⟨ Get the next non-blank non-sign token; set negative appropriately 452 ⟩;
  if (cur_cmd ≥ min_internal) ∧ (cur_cmd ≤ max_internal) then
    begin scan_something_internal(level, negative);
    if cur_val_level ≥ glue_val then
      begin if cur_val_level ≠ level then mu_error;
      return;
      end;
    if cur_val_level = int_val then scan_dimen(mu, false, true)
    else if level = mu_val then mu_error;
    end
  else begin back_input; scan_dimen(mu, false, false);
    if negative then negate(cur_val);
    end;
  ⟨ Create a new glue specification whose width is cur_val; scan for its stretch and shrink components 473 ⟩;
  exit: end;

```

**473.** ⟨ Create a new glue specification whose width is *cur\_val*; scan for its stretch and shrink components 473 ⟩ ≡

```

q ← new_spec(zero_glue); width(q) ← cur_val;
if scan_keyword("plus") then
  begin scan_dimen(mu, true, false); stretch(q) ← cur_val; stretch_order(q) ← cur_order;
  end;
if scan_keyword("minus") then
  begin scan_dimen(mu, true, false); shrink(q) ← cur_val; shrink_order(q) ← cur_order;
  end;
cur_val ← q

```

This code is used in section 472.

**474.** Here's a similar procedure that returns a pointer to a rule node. This routine is called just after T<sub>E</sub>X has seen `\hrule` or `\vrule`; therefore *cur\_cmd* will be either *hrule* or *vrule*. The idea is to store the default rule dimensions in the node, then to override them if 'height' or 'width' or 'depth' specifications are found (in any order).

```

define default_rule = 26214 { 0.4pt }
function scan_rule_spec: pointer;
  label reswitch;
  var q: pointer; { the rule node being created }
  begin q ← new_rule; { width, depth, and height all equal null_flag now }
  if cur_cmd = vrule then width(q) ← default_rule
  else begin height(q) ← default_rule; depth(q) ← 0;
    end;
  reswitch: if scan_keyword("width") then
    begin scan_normal_dimen; width(q) ← cur_val; goto reswitch;
    end;
  if scan_keyword("height") then
    begin scan_normal_dimen; height(q) ← cur_val; goto reswitch;
    end;
  if scan_keyword("depth") then
    begin scan_normal_dimen; depth(q) ← cur_val; goto reswitch;
    end;
  scan_rule_spec ← q;
end;

```

**475. Building token lists.** The token lists for macros and for other things like `\mark` and `\output` and `\write` are produced by a procedure called `scan_toks`.

Before we get into the details of `scan_toks`, let's consider a much simpler task, that of converting the current string into a token list. The `str_toks` function does this; it classifies spaces as type `spacer` and everything else as type `other_char`.

The token list created by `str_toks` begins at `link(temp_head)` and ends at the value `p` that is returned. (If `p = temp_head`, the list is empty.)

```
function str_toks(b : pool_pointer): pointer; { changes the string str_pool[b .. pool_ptr] to a token list }
var p: pointer; { tail of the token list }
    q: pointer; { new node being added to the token list via store_new_token }
    t: halfword; { token being appended }
    k: pool_pointer; { index into str_pool }
begin str_room(1); p ← temp_head; link(p) ← null; k ← b;
while k < pool_ptr do
  begin t ← so(str_pool[k]);
  if multistrlen(ustringcast(str_pool), pool_ptr, k) = 2 then
    begin t ← fromBUFF(ustringcast(str_pool), pool_ptr, k); incr(k);
    end
  else if t = "␣" then t ← space_token
    else t ← other_token + t;
  fast_store_new_token(t); incr(k);
  end;
pool_ptr ← b; str_toks ← p;
end;
```

**476.** The main reason for wanting `str_toks` is the next function, `the_toks`, which has similar input/output characteristics.

This procedure is supposed to scan something like `\skip\count12`, i.e., whatever can follow `\the`, and it constructs a token list containing something like `-3.0pt minus 0.5fill`.

```
function the_toks: pointer;
var old_setting: 0 .. max_selector; { holds selector setting }
    p, q, r: pointer; { used for copying a token list }
    b: pool_pointer; { base of temporary string }
begin get_x_token; scan_something_internal(tok_val, false);
if cur_val_level ≥ ident_val then { Copy the token list 477 }
else begin old_setting ← selector; selector ← new_string; b ← pool_ptr;
  case cur_val_level of
    int_val: print_int(cur_val);
    dimen_val: begin print_scaled(cur_val); print("pt");
    end;
    glue_val: begin print_spec(cur_val, "pt"); delete_glue_ref(cur_val);
    end;
    mu_val: begin print_spec(cur_val, "mu"); delete_glue_ref(cur_val);
    end;
  end; { there are no other cases }
  selector ← old_setting; the_toks ← str_toks(b);
end;
end;
```

```

477.  ⟨ Copy the token list 477 ⟩ ≡
  begin p ← temp_head; link(p) ← null;
  if cur_val.level = ident_val then store_new_token(cs_token_flag + cur_val)
  else if cur_val ≠ null then
    begin r ← link(cur_val); { do not copy the reference count }
    while r ≠ null do
      begin fast_store_new_token(info(r)); r ← link(r);
      end;
    end;
  the_toks ← p;
  end

```

This code is used in section 476.

**478.** Here's part of the *expand* subroutine that we are now ready to complete:

```

procedure ins_the_toks;
  begin link(garbage) ← the_toks; ins_list(link(temp_head));
  end;

```

**479.** The primitives `\number`, `\romannumeral`, `\string`, `\meaning`, `\fontname`, and `\jobname` are defined as follows.

```

define number_code = 0 { command code for \number }
define roman_numeral_code = 1 { command code for \romannumeral }

  end;
  job_name_code: print(job_name);
end { there are no other cases }

```

This code is used in section 481.

**484.** Now we can't postpone the difficulties any longer; we must bravely tackle *scan\_toks*. This function returns a pointer to the tail of a new token list, and it also makes *def\_ref* point to the reference count at the head of that list.

There are two boolean parameters, *macro\_def* and *xpand*. If *macro\_def* is true, the goal is to create the token list for a macro definition; otherwise the goal is to create the token list for some other TEX primitive: `\mark`, `\output`, `\everypar`, `\lowercase`, `\uppercase`, `\message`, `\errmessage`, `\write`, or `\special`. In the latter cases a left brace must be scanned next; this left brace will not be part of the token list, nor will the matching right brace that comes at the end. If *xpand* is false, the token list will simply be copied from the input using *get\_token*. Otherwise all expandable tokens will be expanded until unexpandable tokens are left, except that the results of expanding `\the` are not expanded further. If both *macro\_def* and *xpand* are true, the expansion applies only to the macro body (i.e., to the material following the first *left\_brace* character).

The value of *cur\_cs* when *scan\_toks* begins should be the *eqtb* address of the control sequence to display in "runaway" error messages.

```
function scan_toks(macro_def, xpand : boolean): pointer;
  label found, done, done1, done2;
  var t: halfword; { token representing the highest parameter number }
      s: halfword; { saved token }
      p: pointer; { tail of the token list being built }
      q: pointer; { new node being added to the token list via store_new_token }
      unbalance: halfword; { number of unmatched left braces }
      hash_brace: halfword; { possible '#{ } token }
  begin if macro_def then scanner_status ← defining else scanner_status ← absorbing;
    warning_index ← cur_cs; def_ref ← get_avail; token_ref_count(def_ref) ← null; p ← def_ref;
    hash_brace ← 0; t ← zero_token;

  end
end

```

This code is used in section 488.

491. Another way to create a token list is via the `\read` command. The sixteen files potentially usable for reading appear in the following global variables. The value of `read_open[n]` will be *closed* if stream number *n* has not been opened or if it has been fully read; *just\_open* if an `\openin` but not a `\read` has been done; and *normal* if it is open and ready to read the next line.

```

  define closed = 2 { not open, or at end of file }
  define just_open = 1 { newly opened, first line not yet read }
⟨Global variables 13⟩ +≡
read_file: array [0 .. 15] of alpha_file; { used for \read }
read_open: array [0 .. 16] of normal .. closed; { state of read_file[n] }

```

```

492. ⟨Set initial values of key variables 21⟩ +≡
  for k ← 0 to 16 do read_open[k] ← closed;

```

493. The `read_toks` procedure constructs a token list like that for any macro definition, and makes `cur_val` point to it. Parameter `r` points to the control sequence that will receive this token list.

```

procedure read_toks(n : integer; r : pointer);
  label done;
  var p: pointer; { tail of the token list }
      q: pointer; { new node being added to the token list via store_new_token }
      s: integer; { saved value of align_state }
      m: small_number; { stream number }

  if_dbox_code: print_esc("ifdbox");
  othercases print_esc("if")
endcases;

```

**500.** Conditions can be inside conditions, and this nesting has a stack that is independent of the *save\_stack*.

Four global variables represent the top of the condition stack: *cond\_ptr* points to pushed-down entries, if any; *if\_limit* specifies the largest code of a *fi\_or\_else* command that is syntactically legal; *cur\_if* is the name of the current type of conditional; and *if\_line* is the line number at which it began.

If no conditions are currently in progress, the condition stack has the special state *cond\_ptr* = *null*, *if\_limit* = *normal*, *cur\_if* = 0, *if\_line* = 0. Otherwise *cond\_ptr* points to a two-word node; the *type*, *subtype*, and *link* fields of the first word contain *if\_limit*, *cur\_if*, and *cond\_ptr* at the next level, and the second word contains the corresponding *if\_line*.

```

define if_node_size = 2 { number of words in stack entry for conditionals }
define if_line_field(#) ≡ mem[# + 1].int
define if_code = 1 { code for \if... being evaluated }
define fi_code = 2 { code for \fi }
define else_code = 3 { code for \else }
define or_code = 4 { code for \or }

```

⟨Global variables 13⟩ +≡

```

cond_ptr: pointer; { top of the condition stack }
if_limit: normal .. or_code; { upper bound on fi_or_else codes }
cur_if: small_number; { type of conditional being worked on }
if_line: integer; { line where that conditional began }

```

**501.** ⟨Set initial values of key variables 21⟩ +≡

```

cond_ptr ← null; if_limit ← normal; cur_if ← 0; if_line ← 0;

```

**502.**  $\langle$  Put each of T<sub>E</sub>X's primitives into the hash table 232  $\rangle +\equiv$   
`primitive("fi", fi_or_else, fi_code); text(frozen_fi)  $\leftarrow$  "fi"; eqtb[frozen_fi]  $\leftarrow$  eqtb[cur_val];`  
`primitive("or", fi_or_else, or_code); primitive("else", fi_or_else, else_code);`

**503.**  $\langle$  Cases of *print\_cmd\_chr* for symbolic printing of primitives 233  $\rangle +\equiv$   
`fi_or_else: if chr_code = fi_code then print_esc("fi")`  
`else if chr_code = or_code then print_esc("or")`  
`else print_esc("else");`

**504.** When we skip conditional text, we keep track of the line number where skipping began, for use in error messages.

$\langle$  Global variables 13  $\rangle +\equiv$   
`skip_line: integer; { skipping began here }`

**505.** Here is a procedure that ignores text until coming to an `\or`, `\else`, or `\fi` at level zero of `\if ... \fi` nesting. After it has acted, *cur\_chr* will indicate the token that was found, but *cur\_tok* will not be set (because this makes the procedure run faster).

```

procedure pass_text;
  label done;
  var l: integer; { level of \if ... \fi nesting }
      save_scanner_status: small_number; { scanner_status upon entry }
  begin save_scanner_status  $\leftarrow$  scanner_status; scanner_status  $\leftarrow$  skipping; l  $\leftarrow$  0; skip_line  $\leftarrow$  line;
  loop begin get_next;
    if cur_cmd = fi_or_else then
      begin if l = 0 then goto done;
        if cur_chr = fi_code then decr(l);
        end
      else if cur_cmd = if_test then incr(l);
      end;
  done: scanner_status  $\leftarrow$  save_scanner_status;
  end;

```

**506.** When we begin to process a new `\if`, we set *if\_limit*  $\leftarrow$  *if\_code*; then if `\or` or `\else` or `\fi` occurs before the current `\if` condition has been evaluated, `\relax` will be inserted. For example, a sequence of commands like `\ifvoid1\else... \fi` would otherwise require something after the '1'.

$\langle$  Push the condition stack 506  $\rangle \equiv$   
`begin p  $\leftarrow$  get_node(if_node_size); link(p)  $\leftarrow$  cond_ptr; type(p)  $\leftarrow$  if_limit; subtype(p)  $\leftarrow$  cur_if;`  
`if_line_field(p)  $\leftarrow$  if_line; cond_ptr  $\leftarrow$  p; cur_if  $\leftarrow$  cur_chr; if_limit  $\leftarrow$  if_code; if_line  $\leftarrow$  line;`  
`end`

This code is used in section 509.

**507.**  $\langle$  Pop the condition stack 507  $\rangle \equiv$   
`begin p  $\leftarrow$  cond_ptr; if_line  $\leftarrow$  if_line_field(p); cur_if  $\leftarrow$  subtype(p); if_limit  $\leftarrow$  type(p);`  
`cond_ptr  $\leftarrow$  link(p); free_node(p, if_node_size);`  
`end`

This code is used in sections 509, 511, 520, and 521.

508. Here's a procedure that changes the *if\_limit* code corresponding to a given value of *cond\_ptr*.

```

procedure change_if_limit(l : small_number; p : pointer);
  label exit;
  var q : pointer;
  begin if p = cond_ptr then if_limit ← l { that's the easy case }
  else begin q ← cond_ptr;
    loop begin if q = null then confusion("if");
      if link(q) = p then
        begin type(q) ← l; return;
        end;
      q ← link(q);
      end;
    end;
  exit: end;

```

509. A condition is started when the *expand* procedure encounters an *if\_test* command; in that case *expand* reduces to *conditional*, which is a recursive procedure.

```

procedure conditional;
  label exit, common_ending;
  var b : boolean; { is the condition true? }
  r : "<" .. ">"; { relation to be evaluated }
  m, n : integer; { to be tested against the second operand }
  p, q : pointer; { for traversing token lists in \ifx tests }
  save_scanner_status : small_number; { scanner_status upon entry }
  save_cond_ptr : pointer; { cond_ptr corresponding to this conditional }
  this_if : small_number; { type of this conditional }
  begin ⟨ Push the condition stack 506 ⟩; save_cond_ptr ← cond_ptr; this_if ← cur_chr;
  ⟨ Either process \ifcase or set b to the value of a boolean condition 512 ⟩;
  if tracing_commands > 1 then ⟨ Display the value of b 513 ⟩;
  if b then
    begin change_if_limit(else_code, save_cond_ptr); return; { wait for \else or \fi }
    end;
  ⟨ Skip to \else or \fi, then goto common_ending 511 ⟩;
  common_ending: if cur_chr = fi_code then ⟨ Pop the condition stack 507 ⟩
    else if_limit ← fi_code; { wait for \fi }
  exit: end;

```

510. In a construction like ‘\if\iftrue abc\else d\fi’, the first \else that we come to after learning that the \if is false is not the \else we’re looking for. Hence the following curious logic is needed.

```

511. ⟨ Skip to \else or \fi, then goto common_ending 511 ⟩ ≡
  loop begin pass_text;
    if cond_ptr = save_cond_ptr then
      begin if cur_chr ≠ or_code then goto common_ending;
      print_err("Extra"); print_esc("or");
      help1("I'm ignoring this; it doesn't match any \if."); error;
      end
    else if cur_chr = fi_code then ⟨ Pop the condition stack 507 ⟩;
    end

```

This code is used in section 509.

**512.**  $\langle$  Either process `\ifcase` or set  $b$  to the value of a boolean condition 512  $\rangle \equiv$

  end;
if this_if = if_char_code then b  $\leftarrow$  (n = cur_chr) else b  $\leftarrow$  (m = cur_cmd);
end
```

This code is used in section 512.

**518.** Note that ‘\ifx’ will declare two macros different if one is *long* or *outer* and the other isn’t, even though the texts of the macros are the same.

We need to reset *scanner\_status*, since \outer control sequences are allowed, but we might be scanning a macro definition or preamble.

```

⟨Test if two tokens match 518⟩ ≡
  begin save_scanner_status ← scanner_status; scanner_status ← normal; get_next; n ← cur_cs;
  p ← cur_cmd; q ← cur_chr; get_next;
  if cur_cmd ≠ p then b ← false
  else if cur_cmd < call then b ← (cur_chr = q)
    else ⟨Test if two macro texts match 519⟩;
  scanner_status ← save_scanner_status;
  end

```

This code is used in section 512.

**519.** Note also that ‘\ifx’ decides that macros \a and \b are different in examples like this:

```

      \def\a{\c}    \def\c{}
      \def\b{\d}    \def\d{}

```

```

⟨Test if two macro texts match 519⟩ ≡
  begin p ← link(cur_chr); q ← link(equiv(n)); {omit reference counts}
  if p = q then b ← true
  else begin while (p ≠ null) ∧ (q ≠ null) do
    if info(p) ≠ info(q) then p ← null
    else begin p ← link(p); q ← link(q);
      end;
    b ← ((p = null) ∧ (q = null));
  end;
  end

```

This code is used in section 518.

```

520. ⟨Select the appropriate case and return or goto common_ending 520⟩ ≡
  begin scan_int; n ← cur_val; {n is the number of cases to pass}
  if tracing_commands > 1 then
    begin begin_diagnostic; print("{case□}"); print_int(n); print_char("}"); end_diagnostic(false);
    end;

      else goto common_ending
    else if cur_chr = fi_code then ⟨Pop the condition stack 507⟩;
    end;
  change_if_limit(or_code, save_cond_ptr); return; {wait for \or, \else, or \fi}
  end

```

This code is used in section 512.

**521.** The processing of conditionals is complete except for the following code, which is actually part of *expand*. It comes into play when `\or`, `\else`, or `\fi` is scanned.

```

⟨ Terminate the current conditional and skip to \fi 521 ⟩ ≡
  if cur_chr > if_limit then
    if if_limit = if_code then insert_relax { condition not yet evaluated }
    else begin print_err("Extra_"); print_cmd_chr(fi_or_else, cur_chr);
      help1("I´m_ignoring_ this;_it_doesn´t_match_any_\if."); error;
    end
  else begin while cur_chr ≠ fi_code do pass_text; { skip to \fi }
    ⟨ Pop the condition stack 507 ⟩;
  end

```

This code is used in section 378.

**522. File names.** It's time now to fret about file names. Besides the fact that different operating systems treat files in different ways, we must cope with the fact that completely different naming conventions are used by different groups of people. The following programs show what is required for one particular operating system; similar routines for other systems are not difficult to devise.

T<sub>E</sub>X assumes that a file name has three parts: the name proper; its “extension”; and a “file area” where it is found in an external file system. The extension of an input file or a write file is assumed to be ‘.tex’ unless otherwise specified; it is ‘.log’ on the transcript file that records each run of T<sub>E</sub>X; it is ‘.tfm’ on the font metric files that describe characters in the fonts T<sub>E</sub>X uses; it is ‘.dvi’ on the output files that specify typesetting information; and it is ‘.fmt’ on the format files written by INITEX to initialize T<sub>E</sub>X. The file area can be arbitrary on input files, but files are usually output to the user's current area. If an input file cannot be found on the specified area, T<sub>E</sub>X will look for it on a special system area; this special area is intended for commonly used input files like `webmac.tex`.

Simple uses of T<sub>E</sub>X refer only to file names that have no explicit extension or area. For example, a person usually says ‘\input paper’ or ‘\font\tenrm = helvetica’ instead of ‘\input paper.new’ or ‘\font\tenrm = <csd.knuth>test’. Simple file names are best, because they make the T<sub>E</sub>X source files portable; whenever a file name consists entirely of letters and digits, it should be treated in the same way by all implementations of T<sub>E</sub>X. However, users need the ability to refer to other files in their environment, especially when responding to error messages concerning unopenable files; therefore we want to let them use the syntax that appears in their favorite operating system.

The following procedures don't allow spaces to be part of file names; but some users seem to like names that are spaced-out. System-dependent changes to allow such things should probably be made with reluctance, and only when an entire file name that includes spaces is “quoted” somehow.

**523.** In order to isolate the system-dependent aspects of file names, the system-independent parts of T<sub>E</sub>X are expressed in terms of three system-dependent procedures called *begin\_name*, *more\_name*, and *end\_name*. In essence, if the user-specified characters of the file name are  $c_1 \dots c_n$ , the system-independent driver program does the operations

$$begin\_name; more\_name(c_1); \dots; more\_name(c_n); end\_name.$$

These three procedures communicate with each other via global variables. Afterwards the file name will appear in the string pool as three strings called *cur\_name*, *cur\_area*, and *cur\_ext*; the latter two are null (i.e., “”), unless they were explicitly specified by the user.

Actually the situation is slightly more complicated, because T<sub>E</sub>X needs to know when the file name ends. The *more\_name* routine is a function (with side effects) that returns *true* on the calls *more\_name*( $c_1$ ), ..., *more\_name*( $c_{n-1}$ ). The final call *more\_name*( $c_n$ ) returns *false*; or, it returns *true* and the token following  $c_n$  is something like ‘\hbox’ (i.e., not a character). In other words, *more\_name* is supposed to return *true* unless it is sure that the file name has been completely scanned; and *end\_name* is supposed to be able to finish the assembly of *cur\_name*, *cur\_area*, and *cur\_ext* regardless of whether *more\_name*( $c_n$ ) returned *true* or *false*.

```
< Global variables 13 > +=
cur_name: str_number; { name of file just scanned }
cur_area: str_number; { file area just scanned, or "" }
cur_ext: str_number; { file extension just scanned, or "" }
```

**524.** The file names we shall deal with have the following structure: If the name contains ‘/’ or ‘.’ (for Amiga only), the file area consists of all characters up to and including the final such character; otherwise the file area is null. If the remaining file name contains ‘.’, the file extension consists of all such characters from the last ‘.’ to the end, otherwise the file extension is null.

We can scan such file names easily by using two global variables that keep track of the occurrences of area and extension delimiters:

```

⟨Global variables 13⟩ +≡
area_delimiter: pool_pointer; { the most recent ‘/’, if any }
ext_delimiter: pool_pointer; { the most recent ‘.’, if any }

```

**525.** Input files that can’t be found in the user’s area may appear in a standard system area called *TEX\_area*. Font metric files whose areas are not given explicitly are assumed to appear in a standard system area called *TEX\_font\_area*. These system area names will, of course, vary from place to place.

In C, the default paths are specified separately.

**526.** Here now is the first of the system-dependent routines for file name scanning.

```

procedure begin_name;
begin area_delimiter ← 0; ext_delimiter ← 0; quoted_filename ← false; prev_char ← 0;
end;

```

**527.** And here’s the second. The string pool might change as the file name is being scanned, since a new *\csname* might be entered; therefore we keep *area\_delimiter* and *ext\_delimiter* relative to the beginning of the current string, instead of assigning an absolute address like *pool\_ptr* to them.

```

function more_name(c: ASCII_code): boolean;
begin if (c = "␣") ∧ stop_at_space ∧ (¬quoted_filename) then more_name ← false
else if c = "" then
  begin quoted_filename ← ¬quoted_filename; more_name ← true;
  end
else begin str_room(1); append_char(c); { contribute c to the current string }
  if (IS_DIR_SEP(c) ∧ (not_kanji_char_seq(prev_char, c))) then
    begin area_delimiter ← cur_length; ext_delimiter ← 0;
    end
  else if c = "." then ext_delimiter ← cur_length;
  more_name ← true;
  end;
prev_char ← c;
end;

```

**528.** The third. If a string is already in the string pool, the function *slow\_make\_string* does not create a new string but returns this string number, thus saving string space. Because of this new property of the returned string number it is not possible to apply *flush\_string* to these strings.

```

procedure end_name;
  var temp_str: str_number; { result of file name cache lookups }
      j, s, t: pool_pointer; { running indices }
      must_quote: boolean; { whether we need to quote a string }
  begin if str_ptr + 3 > max_strings then overflow("number_of_strings", max_strings - init_str_ptr);
  str_room(6); { Room for quotes, if needed. }
  { add quotes if needed }
  if area_delimiter ≠ 0 then
    begin { maybe quote cur_area }
    must_quote ← false; s ← str_start[str_ptr]; t ← str_start[str_ptr] + area_delimiter; j ← s;
    while (¬must_quote) ∧ (j < t) do
      begin must_quote ← str_pool[j] = "␣"; incr(j);
      end;
    if must_quote then
      begin for j ← pool_ptr - 1 downto t do str_pool[j + 2] ← str_pool[j];
      str_pool[t + 1] ← "␣";
      for j ← t - 1 downto s do str_pool[j + 1] ← str_pool[j];
      str_pool[s] ← "␣";
      if ext_delimiter ≠ 0 then ext_delimiter ← ext_delimiter + 2;
      area_delimiter ← area_delimiter + 2; pool_ptr ← pool_ptr + 2;
      end;
    end; { maybe quote cur_name }
    s ← str_start[str_ptr] + area_delimiter;
    if ext_delimiter = 0 then t ← pool_ptr
  else t ← str_start[str_ptr] + ext_delimiter - 1;
  must_quote ← false; j ← s;
  while (¬must_quote) ∧ (j < t) do
    begin must_quote ← str_pool[j] = "␣"; incr(j);
    end;
  if must_quote then
    begin for j ← pool_ptr - 1 downto t do str_pool[j + 2] ← str_pool[j];
    str_pool[t + 1] ← "␣";
    for j ← t - 1 downto s do str_pool[j + 1] ← str_pool[j];
    str_pool[s] ← "␣";
    if ext_delimiter ≠ 0 then ext_delimiter ← ext_delimiter + 2;
    pool_ptr ← pool_ptr + 2;
    end;
  if ext_delimiter ≠ 0 then
    begin { maybe quote cur_ext }
    s ← str_start[str_ptr] + ext_delimiter - 1; t ← pool_ptr; must_quote ← false; j ← s;
    while (¬must_quote) ∧ (j < t) do
      begin must_quote ← str_pool[j] = "␣"; incr(j);
      end;
    if must_quote then
      begin str_pool[t + 1] ← "␣";
      for j ← t - 1 downto s do str_pool[j + 1] ← str_pool[j];
      str_pool[s] ← "␣"; pool_ptr ← pool_ptr + 2;
      end;
    end;
  end;

```

```

if area_delimiter = 0 then cur_area ← ""
else begin cur_area ← str_ptr; str_start[str_ptr + 1] ← str_start[str_ptr] + area_delimiter; incr(str_ptr);
  temp_str ← search_string(cur_area);
  if temp_str > 0 then
    begin cur_area ← temp_str; decr(str_ptr); { no flush_string, pool_ptr will be wrong! }
    for j ← str_start[str_ptr + 1] to pool_ptr - 1 do
      begin str_pool[j - area_delimiter] ← str_pool[j];
      end;
    pool_ptr ← pool_ptr - area_delimiter; { update pool_ptr }
    end;
  end;
if ext_delimiter = 0 then
  begin cur_ext ← ""; cur_name ← slow_make_string;
  end
else begin cur_name ← str_ptr;
  str_start[str_ptr + 1] ← str_start[str_ptr] + ext_delimiter - area_delimiter - 1; incr(str_ptr);
  cur_ext ← make_string; decr(str_ptr); { undo extension string to look at name part }
  temp_str ← search_string(cur_name);
  if temp_str > 0 then
    begin cur_name ← temp_str; decr(str_ptr); { no flush_string, pool_ptr will be wrong! }
    for j ← str_start[str_ptr + 1] to pool_ptr - 1 do
      begin str_pool[j - ext_delimiter + area_delimiter + 1] ← str_pool[j];
      end;
    pool_ptr ← pool_ptr - ext_delimiter + area_delimiter + 1; { update pool_ptr }
    end;
  cur_ext ← slow_make_string; { remake extension string }
  end;
end;

```

**529.** Conversely, here is a routine that takes three strings and prints a file name that might have produced them. (The routine is system dependent, because some operating systems put the file area last instead of first.)

```

define check_quoted(#) ≡ { check if string # needs quoting }
  if # ≠ 0 then
    begin j ← str_start[#];
    while (¬must_quote) ∧ (j < str_start[# + 1]) do
      begin must_quote ← str_pool[j] = "□"; incr(j);
      end;
    end
define print_quoted(#) ≡ { print string #, omitting quotes }
  if # ≠ 0 then
    for j ← str_start[#] to str_start[# + 1] - 1 do
      if so(str_pool[j]) ≠ "" then print(so(str_pool[j]))

```

⟨ Basic printing procedures 58 ⟩ +≡

```

procedure print_file_name(n, a, e : integer);
  var must_quote: boolean; { whether to quote the filename }
  j: pool_pointer; { index into str_pool }
  begin must_quote ← false; check_quoted(a); check_quoted(n);
  check_quoted(e); { FIXME: Alternative is to assume that any filename that has to be quoted has at least
    one quoted component...if we pick this, a number of insertions of print_file_name should go away.
    must_quote := ((a;i0) and (str_pool[str_start[a]] = "")) or ((n;i0) and (str_pool[str_start[n]] = "")) or
    ((e;i0) and (str_pool[str_start[e]] = "")); }
  if must_quote then print_char("");
  print_quoted(a); print_quoted(n); print_quoted(e);
  if must_quote then print_char("");
  end;

```

**530.** Another system-dependent routine is needed to convert three internal T<sub>E</sub>X strings into the *name\_of\_file* value that is used to open files. The present code allows both lowercase and uppercase letters in the file name.

```

define append_to_name(#) ≡
  begin c ← #;
  if ¬(c = "") then
    begin incr(k);
    if k ≤ file_name_size then name_of_file[k] ← xchr[c];
    end
  end
procedure pack_file_name(n, a, e : str_number);
  var k: integer; { number of positions filled in name_of_file }
  c: ASCII_code; { character being packed }
  j: pool_pointer; { index into str_pool }
  begin k ← 0;
  if name_of_file then libc_free(name_of_file);
  name_of_file ← xmalloc_array(ASCII_code, length(a) + length(n) + length(e) + 1);
  for j ← str_start[a] to str_start[a + 1] - 1 do append_to_name(so(str_pool[j]));
  for j ← str_start[n] to str_start[n + 1] - 1 do append_to_name(so(str_pool[j]));
  for j ← str_start[e] to str_start[e + 1] - 1 do append_to_name(so(str_pool[j]));
  if k ≤ file_name_size then name_length ← k else name_length ← file_name_size;
  name_of_file[name_length + 1] ← 0;
  end;

```

**531.** A messier routine is also needed, since format file names must be scanned before T<sub>E</sub>X's string mechanism has been initialized. We shall use the global variable *TEX\_format\_default* to supply the text for default system areas and extensions related to format files.

Under UNIX we don't give the area part, instead depending on the path searching that will happen during file opening. Also, the length will be set in the main program.

```
define format_area_length = 0 { length of its area part }
define format_ext_length = 4 { length of its '.fmt' part }
define format_extension = ".fmt" { the extension, as a WEB constant }
```

```
<Global variables 13> +=
format_default_length: integer;
TEX_format_default: cstring;
```

**532.** We set the name of the default format file and the length of that name in C, instead of Pascal, since we want them to depend on the name of the program.

```
533. <Check the "constant" values for consistency 14> +=
if format_default_length > file_name_size then bad ← 31;
```

**534.** Here is the messy routine that was just mentioned. It sets *name\_of\_file* from the first *n* characters of *TEX\_format\_default*, followed by *buffer*[*a* .. *b*], followed by the last *format\_ext\_length* characters of *TEX\_format\_default*.

We dare not give error messages here, since T<sub>E</sub>X calls this routine before the *error* routine is ready to roll. Instead, we simply drop excess characters, since the error will be detected in another way when a strange file name isn't found.

```
procedure pack_buffered_name(n : small_number; a, b : integer);
var k: integer; { number of positions filled in name_of_file }
     c: ASCII_code; { character being packed }
     j: integer; { index into buffer or TEX_format_default }
begin if n + b - a + 1 + format_ext_length > file_name_size then
     b ← a + file_name_size - n - 1 - format_ext_length;
     k ← 0;
if name_of_file then libc_free(name_of_file);
     name_of_file ← xmalloc_array(ASCII_code, n + (b - a + 1) + format_ext_length + 1);
for j ← 1 to n do append_to_name(xord[ucharcast(TEX_format_default[j])]);
for j ← a to b do append_to_name(buffer[j]);
for j ← format_default_length - format_ext_length + 1 to format_default_length do
     append_to_name(xord[ucharcast(TEX_format_default[j])]);
if k ≤ file_name_size then name_length ← k else name_length ← file_name_size;
     name_of_file[name_length + 1] ← 0;
end;
```

**535.** Here is the only place we use *pack\_buffered\_name*. This part of the program becomes active when a “virgin” TeX is trying to get going, just after the preliminary initialization, or when the user is substituting another format file by typing ‘&’ after the initial ‘\*\*’ prompt. The buffer contains the first line of input in *buffer[loc .. (last - 1)]*, where *loc* < *last* and *buffer[loc]* ≠ “\_”.

⟨ Declare the function called *open\_fmt\_file* 535 ⟩ ≡

```

function open_fmt_file: boolean;
  label found, exit;
  var j: 0 .. buf_size; { the first space after the format file name }
  begin j ← loc;
  if buffer[loc] = "&" then
    begin incr(loc); j ← loc; buffer[last] ← "_";
    while buffer[j] ≠ "_" do incr(j);
    pack_buffered_name(0, loc, j - 1); { Kpathsea does everything }
    if w_open_in(fmt_file) then goto found;
    wake_up_terminal; wterm('Sorry, I can't find the format_');
    fputs(stringcast(name_of_file + 1), stdout); wterm(''; will try_');
    fputs(TEX_format_default + 1, stdout); wterm_ln(''.'); update_terminal;
    end; { now pull out all the stops: try for the system plain file }
    pack_buffered_name(format_default_length - format_ext_length, 1, 0);
    if ¬w_open_in(fmt_file) then
      begin wake_up_terminal; wterm('I can't find the format_file_');
      fputs(TEX_format_default + 1, stdout); wterm_ln(''!''); open_fmt_file ← false; return;
      end;
    found: loc ← j; open_fmt_file ← true;
    exit: end;

```

This code is used in section 1316.

**536.** Operating systems often make it possible to determine the exact name (and possible version number) of a file that has been opened. The following routine, which simply makes a T<sub>E</sub>X string from the value of *name\_of\_file*, should ideally be changed to deduce the full name of file *f*, which is the file most recently opened, if it is possible to do this in a Pascal program.

This routine might be called after string memory has overflowed, hence we dare not use ‘*str\_room*’.

```

function make_name_string: str_number;
  var k: 1 .. file_name_size; { index into name_of_file }
      save_area_delimiter, save_ext_delimiter: pool_pointer;
      save_name_in_progress, save_stop_at_space: boolean;
  begin if (pool_ptr + name_length > pool_size) ∨ (str_ptr = max_strings) ∨ (cur_length > 0) then
    make_name_string ← "?"
  else begin for k ← 1 to name_length do append_char(xord[name_of_file[k]]);
    make_name_string ← make_string; { At this point we also set cur_name, cur_ext, and cur_area to
      match the contents of name_of_file. }
    save_area_delimiter ← area_delimiter; save_ext_delimiter ← ext_delimiter;
    save_name_in_progress ← name_in_progress; save_stop_at_space ← stop_at_space;
    name_in_progress ← true; begin_name; stop_at_space ← false; k ← 1;
    while (k ≤ name_length) ∧ (more_name(name_of_file[k])) do incr(k);
    stop_at_space ← save_stop_at_space; end_name; name_in_progress ← save_name_in_progress;
    area_delimiter ← save_area_delimiter; ext_delimiter ← save_ext_delimiter;
  end;
end;
function a_make_name_string(var f: alpha_file): str_number;
  begin a_make_name_string ← make_name_string;
end;
function b_make_name_string(var f: byte_file): str_number;
  begin b_make_name_string ← make_name_string;
end;
function w_make_name_string(var f: word_file): str_number;
  begin w_make_name_string ← make_name_string;
end;

```

**537.** Now let's consider the "driver" routines by which TEX deals with file names in a system-independent manner. First comes a procedure that looks for a file name in the input by calling *get\_x\_token* for the information.

```

procedure scan_file_name;
  label done;
  begin name_in_progress ← true; begin_name; ⟨Get the next non-blank non-call token 417⟩;
  skip_mode ← false;
  loop begin if (cur_cmd = kanji) ∨ (cur_cmd = kana) ∨ (cur_cmd = other_kchar) then { is kanji }
    begin str_room(2); append_char(Hi(cur_chr)); { kanji upper byte }
    append_char(Lo(cur_chr)); { kanji lower byte }
    end
  else if (cur_cmd > other_char) ∨ (cur_chr > 255) then { not a alphabet }
    begin back_input; goto done;
    end { If cur_chr is a space and we're not scanning a token list, check whether we're at the end of
    the buffer. Otherwise we end up adding spurious spaces to file names in some cases. }
  else if ((cur_chr = "␣") ∧ (state ≠ token_list) ∧ (loc > limit)) ∨ ¬more_name(cur_chr) then
    goto done;
  get_x_token;
  end;
done: end_name; name_in_progress ← false; skip_mode ← true;
end;

```

**538.** The global variable *name\_in\_progress* is used to prevent recursive use of *scan\_file\_name*, since the *begin\_name* and other procedures communicate via global variables. Recursion would arise only by devious tricks like '\input\input f'; such attempts at sabotage must be thwarted. Furthermore, *name\_in\_progress* prevents \input from being initiated when a font size specification is being scanned.

Another global variable, *job\_name*, contains the file name that was first \input by the user. This name is extended by '.log' and '.dvi' and '.fmt' in the names of TEX's output files.

```

⟨Global variables 13⟩ +≡
name_in_progress: boolean; { is a file name being scanned? }
job_name: str_number; { principal file name }
log_opened: boolean; { has the transcript file been opened? }

```

**539.** Initially *job\_name* = 0; it becomes nonzero as soon as the true name is known. We have *job\_name* = 0 if and only if the 'log' file has not been opened, except of course for a short time just after *job\_name* has become nonzero.

```

⟨Initialize the output routines 56⟩ +≡
job_name ← 0; name_in_progress ← false; log_opened ← false;

```

**540.** Here is a routine that manufactures the output file names, assuming that *job\_name* ≠ 0. It ignores and changes the current settings of *cur\_area* and *cur\_ext*.

```

define pack_cur_name ≡ pack_file_name(cur_name, cur_area, cur_ext)
procedure pack_job_name(s: str_number); { s = ".log", ".dvi", or format_extension }
  begin cur_area ← ""; cur_ext ← s; cur_name ← job_name; pack_cur_name;
  end;

```

**541.** If some trouble arises when T<sub>E</sub>X tries to open a file, the following routine calls upon the user to supply another file name. Parameter *s* is used in the error message to identify the type of file; parameter *e* is the default extension if none is given. Upon exit from the routine, variables *cur\_name*, *cur\_area*, *cur\_ext*, and *name\_of\_file* are ready for another attempt at file opening.

```

procedure prompt_file_name(s, e : str_number);
  label done;
  var k: 0 .. buf_size; { index into buffer }
      saved_cur_name: str_number; { to catch empty terminal input }
      saved_cur_ext: str_number; { to catch empty terminal input }
      saved_cur_area: str_number; { to catch empty terminal input }
  begin if interaction = scroll_mode then wake_up_terminal;
  if s = "input_file_name" then print_err("I can't find file")
  else print_err("I can't write on file");
  print_file_name(cur_name, cur_area, cur_ext); print("^.");
  if (e = ".tex") ∨ (e = "") then show_context;
  print_ln; print_c_string(prompt_file_name_help_msg);
  if (e ≠ "") then
    begin print("; default file extension is"); print(e); print("");
    end;
  print(""); print_ln; print_nl("Please type another"); print(s);
  if interaction < scroll_mode then fatal_error("*** (job aborted, file error in nonstop mode)");
  saved_cur_name ← cur_name; saved_cur_ext ← cur_ext; saved_cur_area ← cur_area; clear_terminal;
  prompt_input(":"); { Scan file name in the buffer 542 };
  if (length(cur_name) = 0) ∧ (cur_ext = "") ∧ (cur_area = "") then
    begin cur_name ← saved_cur_name; cur_ext ← saved_cur_ext; cur_area ← saved_cur_area;
    end
  else if cur_ext = "" then cur_ext ← e;
  pack_cur_name;
  end;

```

```

542. { Scan file name in the buffer 542 } ≡
  begin begin_name; k ← first;
  while (buffer[k] = " ") ∧ (k < last) do incr(k);
  loop begin if k = last then goto done;
    if ¬more_name(buffer[k]) then goto done;
    incr(k);
  end;
done: end_name;
end

```

This code is used in section 541.

**543.** Here's an example of how these conventions are used. Whenever it is time to ship out a box of stuff, we shall use the macro *ensure\_dvi\_open*.

```

define log_name ≡ termf_log_name
define ensure_dvi_open ≡
  if output_file_name = 0 then
    begin if job_name = 0 then open_log_file;
    pack_job_name(".dvi");
    while ¬b_open_out(dvi_file) do prompt_file_name("file_name_for_output", ".dvi");
    output_file_name ← b_make_name_string(dvi_file);
  end

```

⟨Global variables 13⟩ +≡

```

dvi_file: byte_file; { the device-independent output goes here }
output_file_name: str_number; { full name of the output file }
log_name: str_number; { full name of the log file }

```

**544.** ⟨Initialize the output routines 56⟩ +≡

```

output_file_name ← 0;

```

**545.** The *open\_log\_file* routine is used to open the transcript file and to help it catch up to what has previously been printed on the terminal.

**procedure** open\_log\_file;

```

var old_setting: 0 .. max_selector; { previous selector setting }
    k: 0 .. buf_size; { index into months and buffer }
    l: 0 .. buf_size; { end of first input line }
    months: const_cstring;
begin old_setting ← selector;
if job_name = 0 then job_name ← get_job_name("texput");
pack_job_name(".fls"); recorder_change_filename(stringcast(name_of_file + 1)); pack_job_name(".log");
while ¬a_open_out(log_file) do ⟨Try to get a different log file name 546⟩;
log_name ← a_make_name_string(log_file); selector ← log_only; log_opened ← true;
⟨Print the banner line, including the date and time 547⟩;
if mltx_enabled_p then
  begin wlog_cr; wlog(ˆMLTeX_v2.2_enabledˆ);
  end;
input_stack[input_ptr] ← cur_input; { make sure bottom level is in memory }
print_nl("**"); l ← input_stack[0].limit_field; { last position of first line }
if buffer[l] = end_line_char then decr(l);
for k ← 1 to l do print(buffer[k]);
print_ln; { now the transcript file contains the first line of input }
selector ← old_setting + 2; { log_only or term_and_log }
end;

```

**546.** Sometimes *open\_log\_file* is called at awkward moments when T<sub>E</sub>X is unable to print error messages or even to *show\_context*. The *prompt\_file\_name* routine can result in a *fatal\_error*, but the *error* routine will not be invoked because *log\_opened* will be false.

The normal idea of *batch\_mode* is that nothing at all should be written on the terminal. However, in the unusual case that no log file could be opened, we make an exception and allow an explanatory message to be seen.

Incidentally, the program always refers to the log file as a ‘transcript file’, because some systems cannot use the extension ‘.log’ for this file.

⟨Try to get a different log file name 546⟩ ≡

```
begin selector ← term_only; prompt_file_name("transcript_file_name", ".log");
end
```

This code is used in section 545.

**547.** ⟨Print the banner line, including the date and time 547⟩ ≡

```
begin if src_specials_p ∨ file_line_error_style_p ∨ parse_first_line_p then wlog(banner_k)
else wlog(banner);
wlog(´_´); wlog(conststringcast(get_enc_string)); wlog(´_´); wlog(version_string);
slow_print(format_ident); print("  "); print_int(day); print_char(" ");
months ← ´_JANFEBMARAPRMAJUNJULAUJGSEPNOVDEC´;
for k ← 3 * month - 2 to 3 * month do wlog(months[k]);
print_char(" "); print_int(year); print_char(" "); print_two(time div 60); print_char(":");
print_two(time mod 60);
if shellenabled_p then
  begin wlog_cr; wlog(´_´);
  if restrictedshell then
    begin wlog(´restricted_´);
    end;
  wlog(´\write18_enabled.´);
  end;
if src_specials_p then
  begin wlog_cr; wlog(´_Source_specials_enabled.´);
  end;
if file_line_error_style_p then
  begin wlog_cr; wlog(´_file:line:error_style_messages_enabled.´);
  end;
if parse_first_line_p then
  begin wlog_cr; wlog(´_%&-line_parsing_enabled.´);
  end;
if translate_filename then
  begin wlog_cr; wlog(´_´); fputs(translate_filename, log_file); wlog(´_´);
  end;
end
```

This code is used in section 545.

**548.** Let's turn now to the procedure that is used to initiate file reading when an '`\input`' command is being processed.

```

procedure start_input; { TEX will \input something }
  label done;
  var temp_str: str_number;
  begin scan_file_name; { set cur_name to desired file name }
  pack_cur_name;
  loop begin begin_file_reading; { set up cur_file and new level of input }
    tex_input_type ← 1; { Tell open_input we are \input. }
    { Kpathsea tries all the various ways to get the file. }
    if kpse_in_name_ok(stringcast(name_of_file + 1)) ∧ a_open_in(cur_file, kpse_tex_format) then
      goto done;
    end_file_reading; { remove the level that didn't work }
    prompt_file_name("input_file_name", "");
  end;
done: name ← a_make_name_string(cur_file); source_filename_stack[in_open] ← name;
  full_source_filename_stack[in_open] ← make_full_name_string;
  if name = str_ptr - 1 then { we can try to conserve string pool space now }
    begin temp_str ← search_string(name);
    if temp_str > 0 then
      begin name ← temp_str; flush_string;
      end;
    end;
  if job_name = 0 then
    begin job_name ← get_job_name(cur_name); open_log_file;
    end; { open_log_file doesn't show_context, so limit and loc needn't be set to meaningful values yet }
  if term_offset + length(full_source_filename_stack[in_open]) > max_print_line - 2 then print_ln
  else if (term_offset > 0) ∨ (file_offset > 0) then print_char("□");
  print_char("("); incr(open_parens); slow_print(full_source_filename_stack[in_open]); update_terminal;
  state ← new_line; ⟨ Read the first line of the new file 549 ⟩;
  end;

```

**549.** Here we have to remember to tell the *input\_ln* routine not to start with a *get*. If the file is empty, it is considered to contain a single blank line.

```

⟨ Read the first line of the new file 549 ⟩ ≡
  begin line ← 1;
  if input_ln(cur_file, false) then do_nothing;
  firm_up_the_line;
  if end_line_char_inactive then decr(limit)
  else buffer[limit] ← end_line_char;
  first ← limit + 1; loc ← start;
  end

```

This code is used in section 548.

**550. Font metric data.** T<sub>E</sub>X gets its knowledge about fonts from font metric files, also called TFM files; the ‘T’ in ‘TFM’ stands for T<sub>E</sub>X, but other programs know about them too.

The information in a TFM file appears in a sequence of 8-bit bytes. Since the number of bytes is always a multiple of 4, we could also regard the file as a sequence of 32-bit words, but T<sub>E</sub>X uses the byte interpretation. The format of TFM files was designed by Lyle Ramshaw in 1980. The intent is to convey a lot of different kinds of information in a compact but useful form.

```
<Global variables 13> +=
tfm_file: byte_file;
```

**551.** The first 24 bytes (6 words) of a TFM file contain twelve 16-bit integers that give the lengths of the various subsequent portions of the file. These twelve integers are, in order:

```
lf = length of the entire file, in words;
lh = length of the header data, in words;
bc = smallest character code in the font;
ec = largest character code in the font;
nw = number of words in the width table;
nh = number of words in the height table;
nd = number of words in the depth table;
ni = number of words in the italic correction table;
nl = number of words in the lig/kern table;
nk = number of words in the kern table;
ne = number of words in the extensible character table;
np = number of font parameter words.
```

They are all nonnegative and less than  $2^{15}$ . We must have  $bc - 1 \leq ec \leq 255$ , and

$$lf = 6 + lh + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

Note that a font may contain as many as 256 characters (if  $bc = 0$  and  $ec = 255$ ), and as few as 0 characters (if  $bc = ec + 1$ ).

Incidentally, when two or more 8-bit bytes are combined to form an integer of 16 or more bits, the most significant bytes appear first in the file. This is called BigEndian order.

We use to get T<sub>E</sub>X knowledge about KANJI fonts from JFM files. The JFM format holds more two 16-bit integers,  $id$  and  $nt$ , at the top of the file.

```
id = identification code of the file;
nt = number of words in the char.type table;
```

The identification byte,  $id$  equals 11 or 9. When T<sub>E</sub>X read a font file, the  $id$  equals 11 or 9 then the font is the JFM, othercases it is the TFM file. The TFM holds  $lf$  at the same position of  $id$ , usually it take a larger number than 9 or 11. The  $nt$  is nonngative and less than  $2^{15}$ .

We must have  $ec = 0$ ,

$$lf = 7 + lh + nt + (ec - bc + 1) + nw + nh + nd + ni + nl + nk + ne + np.$$

```
define yoko_jfm_id = 11 { for ‘yoko-kumi’ fonts }
define tate_jfm_id = 9 { for ‘tate-kumi’ fonts }
```

**552.** The rest of the TFM file may be regarded as a sequence of ten data arrays having the informal specification

```

header : array [0 .. lh - 1] of stuff
char_info : array [bc .. ec] of char_info_word
width : array [0 .. nw - 1] of fix_word
height : array [0 .. nh - 1] of fix_word
depth : array [0 .. nd - 1] of fix_word
italic : array [0 .. ni - 1] of fix_word
lig_kern : array [0 .. nl - 1] of lig_kern_command
kern : array [0 .. nk - 1] of fix_word
exten : array [0 .. ne - 1] of extensible_recipe
param : array [1 .. np] of fix_word

```

The most important data type used here is a *fix\_word*, which is a 32-bit representation of a binary fraction. A *fix\_word* is a signed quantity, with the two's complement of the entire word used to represent negation. Of the 32 bits in a *fix\_word*, exactly 12 are to the left of the binary point; thus, the largest *fix\_word* value is  $2048 - 2^{-20}$ , and the smallest is  $-2048$ . We will see below, however, that all but two of the *fix\_word* values must lie between  $-16$  and  $+16$ .

**553.** The first data array is a block of header information, which contains general facts about the font. The header must contain at least two words, *header*[0] and *header*[1], whose meaning is explained below. Additional header information of use to other software routines might also be included, but T<sub>E</sub>X82 does not need to know about such details. For example, 16 more words of header information are in use at the Xerox Palo Alto Research Center; the first ten specify the character coding scheme used (e.g., ‘XEROX text’ or ‘T<sub>E</sub>X math symbols’), the next five give the font identifier (e.g., ‘HELVETICA’ or ‘CMSY’), and the last gives the “face byte.” The program that converts DVI files to Xerox printing format gets this information by looking at the TFM file, which it needs to read anyway because of other information that is not explicitly repeated in DVI format.

*header*[0] is a 32-bit check sum that T<sub>E</sub>X will copy into the DVI output file. Later on when the DVI file is printed, possibly on another computer, the actual font that gets used is supposed to have a check sum that agrees with the one in the TFM file used by T<sub>E</sub>X. In this way, users will be warned about potential incompatibilities. (However, if the check sum is zero in either the font file or the TFM file, no check is made.) The actual relation between this check sum and the rest of the TFM file is not important; the check sum is simply an identification number with the property that incompatible fonts almost always have distinct check sums.

*header*[1] is a *fix\_word* containing the design size of the font, in units of T<sub>E</sub>X points. This number must be at least 1.0; it is fairly arbitrary, but usually the design size is 10.0 for a “10 point” font, i.e., a font that was designed to look best at a 10-point size, whatever that really means. When a T<sub>E</sub>X user asks for a font ‘at  $\delta$  pt’, the effect is to override the design size and replace it by  $\delta$ , and to multiply the *x* and *y* coordinates of the points in the font image by a factor of  $\delta$  divided by the design size. All other dimensions in the TFM file are *fix\_word* numbers in design-size units, with the exception of *param*[1] (which denotes the slant ratio). Thus, for example, the value of *param*[6], which defines the em unit, is often the *fix\_word* value  $2^{20} = 1.0$ , since many fonts have a design size equal to one em. The other dimensions must be less than 16 design-size units in absolute value; thus, *header*[1] and *param*[1] are the only *fix\_word* entries in the whole TFM file whose first byte might be something besides 0 or 255.

**554.** Next comes the *char\_info* array, which contains one *char\_info\_word* per character. Each word in this part of the file contains six fields packed into four bytes as follows.

first byte: *width\_index* (8 bits)

second byte: *height\_index* (4 bits) times 16, plus *depth\_index* (4 bits)

third byte: *italic\_index* (6 bits) times 4, plus *tag* (2 bits)

fourth byte: *remainder* (8 bits)

The actual width of a character is  $width[width\_index]$ , in design-size units; this is a device for compressing information, since many characters have the same width. Since it is quite common for many characters to have the same height, depth, or italic correction, the TFM format imposes a limit of 16 different heights, 16 different depths, and 64 different italic corrections.

The italic correction of a character has two different uses. (a) In ordinary text, the italic correction is added to the width only if the T<sub>E</sub>X user specifies ‘\’ after the character. (b) In math formulas, the italic correction is always added to the width, except with respect to the positioning of subscripts.

Incidentally, the relation  $width[0] = height[0] = depth[0] = italic[0] = 0$  should always hold, so that an index of zero implies a value of zero. The *width\_index* should never be zero unless the character does not exist in the font, since a character is valid if and only if it lies between *bc* and *ec* and has a nonzero *width\_index*.

**555.** The *tag* field in a *char\_info\_word* has four values that explain how to interpret the *remainder* field.

*tag* = 0 (*no\_tag*) means that *remainder* is unused.

*tag* = 1 (*lig\_tag*) means that this character has a ligature/kerning program starting at position *remainder* in the *lig\_kern* array.

*tag* = 2 (*list\_tag*) means that this character is part of a chain of characters of ascending sizes, and not the largest in the chain. The *remainder* field gives the character code of the next larger character.

*tag* = 3 (*ext\_tag*) means that this character code represents an extensible character, i.e., a character that is built up of smaller pieces so that it can be made arbitrarily large. The pieces are specified in *exten[remainder]*.

Characters with *tag* = 2 and *tag* = 3 are treated as characters with *tag* = 0 unless they are used in special circumstances in math formulas. For example, the `\sum` operation looks for a *list\_tag*, and the `\left` operation looks for both *list\_tag* and *ext\_tag*.

If the JFM, the *lig\_tag* is called *gk\_tag*. The *gk\_tag* means that this character has a glue/kerning program starting at position *remainder* in the *glue\_kern* array. And a JFM not used *tag* = 2 and *tag* = 3.

```

define no_tag = 0 { vanilla character }
define lig_tag = 1 { character has a ligature/kerning program }
define gk_tag = 1 { character has a glue/kerning program }
define list_tag = 2 { character has a successor in a charlist }
define ext_tag = 3 { character is extensible }

```

**556.** The *lig\_kern* array contains instructions in a simple programming language that explains what to do for special letter pairs. Each word in this array is a *lig\_kern\_command* of four bytes.

first byte: *skip\_byte*, indicates that this is the final program step if the byte is 128 or more, otherwise the next step is obtained by skipping this number of intervening steps.

second byte: *next\_char*, “if *next\_char* follows the current character, then perform the operation and stop, otherwise continue.”

third byte: *op\_byte*, indicates a ligature step if less than 128, a kern step otherwise.

fourth byte: *remainder*.

In a kern step, an additional space equal to  $kern[256 * (op\_byte - 128) + remainder]$  is inserted between the current character and *next\_char*. This amount is often negative, so that the characters are brought closer together by kerning; but it might be positive.

There are eight kinds of ligature steps, having *op\_byte* codes  $4a+2b+c$  where  $0 \leq a \leq b+c$  and  $0 \leq b, c \leq 1$ . The character whose code is *remainder* is inserted between the current character and *next\_char*; then the current character is deleted if  $b = 0$ , and *next\_char* is deleted if  $c = 0$ ; then we pass over  $a$  characters to reach the next current character (which may have a ligature/kerning program of its own).

If the very first instruction of the *lig\_kern* array has *skip\_byte* = 255, the *next\_char* byte is the so-called right boundary character of this font; the value of *next\_char* need not lie between  $bc$  and  $ec$ . If the very last instruction of the *lig\_kern* array has *skip\_byte* = 255, there is a special ligature/kerning program for a left boundary character, beginning at location  $256 * op\_byte + remainder$ . The interpretation is that T<sub>E</sub>X puts implicit boundary characters before and after each consecutive string of characters from the same font. These implicit characters do not appear in the output, but they can affect ligatures and kerning.

If the very first instruction of a character’s *lig\_kern* program has *skip\_byte* > 128, the program actually begins in location  $256 * op\_byte + remainder$ . This feature allows access to large *lig\_kern* arrays, because the first instruction must otherwise appear in a location  $\leq 255$ .

Any instruction with *skip\_byte* > 128 in the *lig\_kern* array must satisfy the condition

$$256 * op\_byte + remainder < nl.$$

If such an instruction is encountered during normal program execution, it denotes an unconditional halt; no ligature or kerning command is performed.

```

define stop_flag ≡ qi(128)  { value indicating ‘STOP’ in a lig/kern program }
define kern_flag ≡ qi(128)  { op code for a kern step }
define skip_byte(#) ≡ #.b0
define next_char(#) ≡ #.b1
define op_byte(#) ≡ #.b2
define rem_byte(#) ≡ #.b3

```

**557.** Extensible characters are specified by an *extensible\_recipe*, which consists of four bytes called *top*, *mid*, *bot*, and *rep* (in this order). These bytes are the character codes of individual pieces used to build up a large symbol. If *top*, *mid*, or *bot* are zero, they are not present in the built-up result. For example, an extensible vertical line is like an extensible bracket, except that the top and bottom pieces are missing.

Let  $T$ ,  $M$ ,  $B$ , and  $R$  denote the respective pieces, or an empty box if the piece isn’t present. Then the extensible characters have the form  $TR^kMR^kB$  from top to bottom, for some  $k \geq 0$ , unless  $M$  is absent; in the latter case we can have  $TR^kB$  for both even and odd values of  $k$ . The width of the extensible character is the width of  $R$ ; and the height-plus-depth is the sum of the individual height-plus-depths of the components used, since the pieces are butted together in a vertical list.

```

define ext_top(#) ≡ #.b0  { top piece in a recipe }
define ext_mid(#) ≡ #.b1  { mid piece in a recipe }
define ext_bot(#) ≡ #.b2  { bot piece in a recipe }
define ext_rep(#) ≡ #.b3  { rep piece in a recipe }

```

**558.** The final portion of a TFM file is the *param* array, which is another sequence of *fix\_word* values.

*param*[1] = *slant* is the amount of italic slant, which is used to help position accents. For example, *slant* = .25 means that when you go up one unit, you also go .25 units to the right. The *slant* is a pure number; it's the only *fix\_word* other than the design size itself that is not scaled by the design size.

*param*[2] = *space* is the normal spacing between words in text. Note that character "␣" in the font need not have anything to do with blank spaces.

*param*[3] = *space\_stretch* is the amount of glue stretching between words.

*param*[4] = *space\_shrink* is the amount of glue shrinking between words.

*param*[5] = *x\_height* is the size of one ex in the font; it is also the height of letters for which accents don't have to be raised or lowered.

*param*[6] = *quad* is the size of one em in the font.

*param*[7] = *extra\_space* is the amount added to *param*[2] at the ends of sentences.

If fewer than seven parameters are present, T<sub>E</sub>X sets the missing parameters to zero. Fonts used for math symbols are required to have additional parameter information, which is explained later.

```

define slant_code = 1
define space_code = 2
define space_stretch_code = 3
define space_shrink_code = 4
define x_height_code = 5
define quad_code = 6
define extra_space_code = 7

```

**559.** So that is what TFM files hold. Since T<sub>E</sub>X has to absorb such information about lots of fonts, it stores most of the data in a large array called *font\_info*. Each item of *font\_info* is a *memory\_word*; the *fix\_word* data gets converted into *scaled* entries, while everything else goes into words of type *four\_quarters*.

When the user defines `\font\font`, say, T<sub>E</sub>X assigns an internal number to the user's font `\font`. Adding this number to *font\_id\_base* gives the *eqtb* location of a "frozen" control sequence that will always select the font.

```

⟨Types in the outer block 18⟩ +≡
internal_font_number = integer; { font in a char_node }
font_index = integer; { index into font_info }
nine_bits = min_quarterword .. non_char;

```

**560.** Here now is the (rather formidable) array of font arrays.

```

define non_char ≡ qi(256) { a halfword code that can't match a real character }
define non_address = 0 { a spurious bchar_label }

⟨Global variables 13⟩ +≡
font_info: ↑memory_word; { pTeX: use halfword for char_type table. }
font_dir: ↑eight_bits; { pTeX: direction of fonts, 0 is default, 1 is Yoko, 2 is Tate }
font_num_ext: ↑integer; { pTeX: number of the char_type table. }
    { the big collection of font data }
fmem_ptr: font_index; { first unused word of font_info }
font_ptr: internal_font_number; { largest internal font number in use }
font_check: ↑four_quarters; { check sum }
font_size: ↑scaled; { "at" size }
font_dsize: ↑scaled; { "design" size }
font_params: ↑font_index; { how many font parameters are present }
font_name: ↑str_number; { name of the font }
font_area: ↑str_number; { area of the font }
font_bc: ↑eight_bits; { beginning (smallest) character code }
font_ec: ↑eight_bits; { ending (largest) character code }
font_glue: ↑pointer; { glue specification for interword space, null if not allocated }
font_used: ↑boolean; { has a character from this font actually appeared in the output? }
hyphen_char: ↑integer; { current \hyphenchar values }
skew_char: ↑integer; { current \skewchar values }
bchar_label: ↑font_index;
    { start of lig_kern program for left boundary character, non_address if there is none }
font_bchar: ↑nine_bits; { right boundary character, non_char if there is none }
font_false_bchar: ↑nine_bits; { font_bchar if it doesn't exist in the font, otherwise non_char }

```

**561.** Besides the arrays just enumerated, we have directory arrays that make it easy to get at the individual entries in *font\_info*. For example, the *char\_info* data for character *c* in font *f* will be in *font\_info*[*char\_base*[*f*] + *c*].*qqqq*; and if *w* is the *width\_index* part of this word (the *b0* field), the width of the character is *font\_info*[*width\_base*[*f*] + *w*].*sc*. (These formulas assume that *min\_quarterword* has already been added to *c* and to *w*, since T<sub>E</sub>X stores its quarterwords that way.)

```

⟨Global variables 13⟩ +≡
char_base: ↑integer; { base addresses for char_info }
ctype_base: ↑integer; { pTeX: base addresses for KANJI character type parameters }
width_base: ↑integer; { base addresses for widths }
height_base: ↑integer; { base addresses for heights }
depth_base: ↑integer; { base addresses for depths }
italic_base: ↑integer; { base addresses for italic corrections }
lig_kern_base: ↑integer; { base addresses for ligature/kerning programs }
kern_base: ↑integer; { base addresses for kerns }
exten_base: ↑integer; { base addresses for extensible recipes }
param_base: ↑integer; { base addresses for font parameters }

```

**562.** ⟨Set initial values of key variables 21⟩ +≡

**563.** T<sub>E</sub>X always knows at least one font, namely the null font. It has no characters, and its seven parameters are all equal to zero.

⟨Initialize table entries (done by INITEX only) 170⟩ +≡

**564.** ⟨ Put each of T<sub>E</sub>X's primitives into the hash table 232 ⟩ +≡  
*primitive*("nullfont", *set\_font*, *null\_font*); *text*(*frozen\_null\_font*) ← "nullfont";  
*eqtb*[*frozen\_null\_font*] ← *eqtb*[*cur\_val*];

**565.** Of course we want to define macros that suppress the detail of how font information is actually packed, so that we don't have to write things like

$$font\_info[width\_base[f] + font\_info[char\_base[f] + c].qqqq.b0].sc$$

too often. The WEB definitions here make  $char\_info(f)(c)$  the *four-quarters* word of font information corresponding to character  $c$  of font  $f$ . If  $q$  is such a word,  $char\_width(f)(q)$  will be the character's width; hence the long formula above is at least abbreviated to

$$char\_width(f)(char\_info(f)(c)).$$

Usually, of course, we will fetch  $q$  first and look at several of its fields at the same time.

The italic correction of a character will be denoted by  $char\_italic(f)(q)$ , so it is analogous to  $char\_width$ . But we will get at the height and depth in a slightly different way, since we usually want to compute both height and depth if we want either one. The value of  $height\_depth(q)$  will be the 8-bit quantity

$$b = height\_index \times 16 + depth\_index,$$

and if  $b$  is such a byte we will write  $char\_height(f)(b)$  and  $char\_depth(f)(b)$  for the height and depth of the character  $c$  for which  $q = char\_info(f)(c)$ . Got that?

The tag field will be called  $char\_tag(q)$ ; the remainder byte will be called  $rem\_byte(q)$ , using a macro that we have already defined above.

Access to a character's *width*, *height*, *depth*, and *tag* fields is part of T<sub>E</sub>X's inner loop, so we want these macros to produce code that is as fast as possible under the circumstances.

MLT<sub>E</sub>X will assume that a character  $c$  exists iff either exists in the current font or a character substitution definition for this character was defined using `\charsubdef`. To avoid the distinction between these two cases, MLT<sub>E</sub>X introduces the notion "effective character" of an input character  $c$ . If  $c$  exists in the current font, the effective character of  $c$  is the character  $c$  itself. If it doesn't exist but a character substitution is defined, the effective character of  $c$  is the base character defined in the character substitution. If there is an effective character for a non-existing character  $c$ , the "virtual character"  $c$  will get appended to the horizontal lists.

The effective character is used within  $char\_info$  to access appropriate character descriptions in the font. For example, when calculating the width of a box, MLT<sub>E</sub>X will use the metrics of the effective characters. For the case of a substitution, MLT<sub>E</sub>X uses the metrics of the base character, ignoring the metrics of the accent character.

If character substitutions are changed, it will be possible that a character  $c$  neither exists in a font nor there is a valid character substitution for  $c$ . To handle these cases  $effective\_char$  should be called with its first argument set to *true* to ensure that it will still return an existing character in the font. If neither  $c$  nor the substituted base character in the current character substitution exists,  $effective\_char$  will output a warning and return the character  $font\_bc[f]$  (which is incorrect, but can not be changed within the current framework).

Sometimes character substitutions are unwanted, therefore the original definition of  $char\_info$  can be used using the macro  $orig\_char\_info$ . Operations in which character substitutions should be avoided are, for example, loading a new font and checking the font metric information in this font, and character accesses in math mode.

```

define char_list_exists(#) ≡ (char_sub_code(#) > hi(0))

define quad ≡ param(quad_code) { one em }
define extra_space ≡ param(extra_space_code) { additional space at end of sentence }

```

⟨The em width for *cur\_font* 569⟩ ≡

```
quad(cur_font)
```

This code is used in section 466.

**570.**  $\langle$  The x-height for *cur\_font* 570  $\rangle \equiv$   
 $x\_height(cur\_font)$

This code is used in section 466.

**571.** T<sub>E</sub>X checks the information of a TFM file for validity as the file is being read in, so that no further checks will be needed when typesetting is going on. The somewhat tedious subroutine that does this is called *read\_font\_info*. It has four parameters: the user font identifier *u*, the file name and area strings *nom* and *aire*, and the “at” size *s*. If *s* is negative, it’s the negative of a scale factor to be applied to the design size; *s* = −1000 is the normal case. Otherwise *s* will be substituted for the design size; in this case, *s* must be positive and less than 2048 pt (i.e., it must be less than 2<sup>27</sup> when considered as an integer).

The subroutine opens and closes a global file variable called *tfm\_file*. It returns the value of the internal font number that was just loaded. If an error is detected, an error message is issued and no font information is stored; *null\_font* is returned in this case.

```

define bad_tfm = 11 { label for read_font_info }
define abort  $\equiv$  goto bad_tfm { do this when the TFM data is wrong }
 $\langle$  Declare additional functions for MLTEX 1407  $\rangle$

**591.**  $\langle$  Increase the number of parameters in the last font 591  $\rangle \equiv$   
**begin repeat** if  $fmem\_ptr = font\_mem\_size$  **then**  $overflow("font\_memory", font\_mem\_size);$   
 $font\_info[fmem\_ptr].sc \leftarrow 0; incr(fmem\_ptr); incr(font\_params[f]);$   
**until**  $n = font\_params[f];$   
 $cur\_val \leftarrow fmem\_ptr - 1; \{ \text{this equals } param\_base[f] + font\_params[f] \}$   
**end**

This code is used in section 589.

**592.** When T<sub>E</sub>X wants to typeset a character that doesn't exist, the character node is not created; thus the output routine can assume that characters exist when it sees them. The following procedure prints a warning message unless the user has suppressed it.

```
define  $print\_lc\_hex(\#) \equiv l \leftarrow \#;$   

    if  $l < 10$  then  $print\_char(l + "0")$  else  $print\_char(l - 10 + "a")$   

procedure  $char\_warning(f : internal\_font\_number; c : eight\_bits);$   

var  $l : 0 .. 255;$  { small indices or counters }  

begin if  $tracing\_lost\_chars > 0$  then  

    begin  $begin\_diagnostic;$   $print\_nl("Missing\_character: \_There\_is\_no\_");$   

    if  $(c < "\_") \vee (c > "\^")$  then  

        begin  $print\_char("\^"); print\_char("\^");$   

        if  $c < 64$  then  $print\_char(c + 64)$   

        else if  $c < 128$  then  $print\_char(c - 64)$   

        else begin  $print\_lc\_hex(c \text{ div } 16); print\_lc\_hex(c \text{ mod } 16);$   

        end  

    end  

    else  $print\_ASCII(c);$   

 $print("\_in\_font\_"); slow\_print(font\_name[f]); print\_char("!"); end\_diagnostic(false);$   

end;  

end;
```

**593.** Here is a function that returns a pointer to a character node for a given character in a given font. If that character doesn't exist, *null* is returned instead.

This allows a character node to be used if there is an equivalent in the *char\_sub\_code* list.

```
function  $new\_character(f : internal\_font\_number; c : eight\_bits): pointer;$   

label  $exit;$   

var  $p: pointer;$  { newly allocated node }  

 $ec: quarterword;$  { effective character of  $c$  }  

begin  $ec \leftarrow effective\_char(false, f, qi(c));$   

if  $font\_bc[f] \leq qo(ec)$  then  

    if  $font\_ec[f] \geq qo(ec)$  then  

        if  $char\_exists(orig\_char\_info(f)(ec))$  then { N.B.: not char_info }  

        begin  $p \leftarrow get\_avail; font(p) \leftarrow f; character(p) \leftarrow qi(c); new\_character \leftarrow p; return;$   

        end;  

     $char\_warning(f, c); new\_character \leftarrow null;$   

 $exit: end;$ 
```

**594. Device-independent file format.** The most important output produced by a run of T<sub>E</sub>X is the “device independent” (DVI) file that specifies where characters and rules are to appear on printed pages. The form of these files was designed by David R. Fuchs in 1979. Almost any reasonable typesetting device can be driven by a program that takes DVI files as input, and dozens of such DVI-to-whatever programs have been written. Thus, it is possible to print the output of T<sub>E</sub>X on many different kinds of equipment, using T<sub>E</sub>X as a device-independent “front end.”

A DVI file is a stream of 8-bit bytes, which may be regarded as a series of commands in a machine-like language. The first byte of each command is the operation code, and this code is followed by zero or more bytes that provide parameters to the command. The parameters themselves may consist of several consecutive bytes; for example, the ‘*set.rule*’ command has two parameters, each of which is four bytes long. Parameters are usually regarded as nonnegative integers; but four-byte-long parameters, and shorter parameters that denote distances, can be either positive or negative. Such parameters are given in two’s complement notation. For example, a two-byte-long distance parameter has a value between  $-2^{15}$  and  $2^{15} - 1$ . As in TFM files, numbers that occupy more than one byte position appear in BigEndian order.

A DVI file consists of a “preamble,” followed by a sequence of one or more “pages,” followed by a “postamble.” The preamble is simply a *pre* command, with its parameters that define the dimensions used in the file; this must come first. Each “page” consists of a *bop* command, followed by any number of other commands that tell where characters are to be placed on a physical page, followed by an *eop* command. The pages appear in the order that T<sub>E</sub>X generated them. If we ignore *nop* commands and *fmt.def* commands (which are allowed between any two commands in the file), each *eop* command is immediately followed by a *bop* command, or by a *post* command; in the latter case, there are no more pages in the file, and the remaining bytes form the postamble. Further details about the postamble will be explained later.

Some parameters in DVI commands are “pointers.” These are four-byte quantities that give the location number of some other byte in the file; the first byte is number 0, then comes number 1, and so on. For example, one of the parameters of a *bop* command points to the previous *bop*; this makes it feasible to read the pages in backwards order, in case the results are being directed to a device that stacks its output face up. Suppose the preamble of a DVI file occupies bytes 0 to 99. Now if the first page occupies bytes 100 to 999, say, and if the second page occupies bytes 1000 to 1999, then the *bop* that starts in byte 1000 points to 100 and the *bop* that starts in byte 2000 points to 1000. (The very first *bop*, i.e., the one starting in byte 100, has a pointer of  $-1$ .)

**595.** The DVI format is intended to be both compact and easily interpreted by a machine. Compactness is achieved by making most of the information implicit instead of explicit. When a DVI-reading program reads the commands for a page, it keeps track of several quantities: (a) The current font *f* is an integer; this value is changed only by *fmt* and *fmt.num* commands. (b) The current position on the page is given by two numbers called the horizontal and vertical coordinates, *h* and *v*. Both coordinates are zero at the upper left corner of the page; moving to the right corresponds to increasing the horizontal coordinate, and moving down corresponds to increasing the vertical coordinate. Thus, the coordinates are essentially Cartesian, except that vertical directions are flipped; the Cartesian version of  $(h, v)$  would be  $(h, -v)$ . (c) The current spacing amounts are given by four numbers *w*, *x*, *y*, and *z*, where *w* and *x* are used for horizontal spacing and where *y* and *z* are used for vertical spacing. (d) There is a stack containing  $(h, v, w, x, y, z)$  values; the DVI commands *push* and *pop* are used to change the current level of operation. Note that the current font *f* is not pushed and popped; the stack contains only information about positioning.

The values of *h*, *v*, *w*, *x*, *y*, and *z* are signed integers having up to 32 bits, including the sign. Since they represent physical distances, there is a small unit of measurement such that increasing *h* by 1 means moving a certain tiny distance to the right. The actual unit of measurement is variable, as explained below; T<sub>E</sub>X sets things up so that its DVI output is in sp units, i.e., scaled points, in agreement with all the *scaled* dimensions in T<sub>E</sub>X’s data structures.

**596.** Here is a list of all the commands that may appear in a DVI file. Each command is specified by its symbolic name (e.g., *bop*), its opcode byte (e.g., 139), and its parameters (if any). The parameters are followed by a bracketed number telling how many bytes they occupy; for example, ‘*p*[4]’ means that parameter *p* is four bytes long.

*set\_char\_0* 0. Typeset character number 0 from font *f* such that the reference point of the character is at (*h*, *v*). Then increase *h* by the width of that character. Note that a character may have zero or negative width, so one cannot be sure that *h* will advance after this command; but *h* usually does increase.

*set\_char\_1* through *set\_char\_127* (opcodes 1 to 127). Do the operations of *set\_char\_0*; but use the character whose number matches the opcode, instead of character 0.

*set1* 128 *c*[1]. Same as *set\_char\_0*, except that character number *c* is typeset. T<sub>E</sub>X82 uses this command for characters in the range  $128 \leq c < 256$ .

*set2* 129 *c*[2]. Same as *set1*, except that *c* is two bytes long, so it is in the range  $0 \leq c < 65536$ . T<sub>E</sub>X82 never uses this command, but it should come in handy for extensions of T<sub>E</sub>X that deal with oriental languages.

*set3* 130 *c*[3]. Same as *set1*, except that *c* is three bytes long, so it can be as large as  $2^{24} - 1$ . Not even the Chinese language has this many characters, but this command might prove useful in some yet unforeseen extension.

*set4* 131 *c*[4]. Same as *set1*, except that *c* is four bytes long. Imagine that.

*set\_rule* 132 *a*[4] *b*[4]. Typeset a solid black rectangle of height *a* and width *b*, with its bottom left corner at (*h*, *v*). Then set  $h \leftarrow h + b$ . If either  $a \leq 0$  or  $b \leq 0$ , nothing should be typeset. Note that if  $b < 0$ , the value of *h* will decrease even though nothing else happens. See below for details about how to typeset rules so that consistency with METAFONT is guaranteed.

*put1* 133 *c*[1]. Typeset character number *c* from font *f* such that the reference point of the character is at (*h*, *v*). (The ‘put’ commands are exactly like the ‘set’ commands, except that they simply put out a character or a rule without moving the reference point afterwards.)

*put2* 134 *c*[2]. Same as *set2*, except that *h* is not changed.

*put3* 135 *c*[3]. Same as *set3*, except that *h* is not changed.

*put4* 136 *c*[4]. Same as *set4*, except that *h* is not changed.

*put\_rule* 137 *a*[4] *b*[4]. Same as *set\_rule*, except that *h* is not changed.

*nop* 138. No operation, do nothing. Any number of *nop*’s may occur between DVI commands, but a *nop* cannot be inserted between a command and its parameters or between two parameters.

*bop* 139 *c*<sub>0</sub>[4] *c*<sub>1</sub>[4] ... *c*<sub>9</sub>[4] *p*[4]. Beginning of a page: Set  $(h, v, w, x, y, z) \leftarrow (0, 0, 0, 0, 0, 0)$  and set the stack empty. Set the current font *f* to an undefined value. The ten *c*<sub>*i*</sub> parameters hold the values of `\count0` ... `\count9` in T<sub>E</sub>X at the time `\shipout` was invoked for this page; they can be used to identify pages, if a user wants to print only part of a DVI file. The parameter *p* points to the previous *bop* in the file; the first *bop* has *p* = -1.

*eop* 140. End of page: Print what you have read since the previous *bop*. At this point the stack should be empty. (The DVI-reading programs that drive most output devices will have kept a buffer of the material that appears on the page that has just ended. This material is largely, but not entirely, in order by *v* coordinate and (for fixed *v*) by *h* coordinate; so it usually needs to be sorted into some order that is appropriate for the device in question.)

*push* 141. Push the current values of (*h*, *v*, *w*, *x*, *y*, *z*) onto the top of the stack; do not change any of these values. Note that *f* is not pushed.

*pop* 142. Pop the top six values off of the stack and assign them respectively to (*h*, *v*, *w*, *x*, *y*, *z*). The number of pops should never exceed the number of pushes, since it would be highly embarrassing if the stack were empty at the time of a *pop* command.

*right1* 143 *b*[1]. Set  $h \leftarrow h + b$ , i.e., move right *b* units. The parameter is a signed number in two’s complement notation,  $-128 \leq b < 128$ ; if  $b < 0$ , the reference point moves left.

- right2* 144 *b*[2]. Same as *right1*, except that *b* is a two-byte quantity in the range  $-32768 \leq b < 32768$ .
- right3* 145 *b*[3]. Same as *right1*, except that *b* is a three-byte quantity in the range  $-2^{23} \leq b < 2^{23}$ .
- right4* 146 *b*[4]. Same as *right1*, except that *b* is a four-byte quantity in the range  $-2^{31} \leq b < 2^{31}$ .
- w0* 147. Set  $h \leftarrow h + w$ ; i.e., move right *w* units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how *w* gets particular values.
- w1* 148 *b*[1]. Set  $w \leftarrow b$  and  $h \leftarrow h + b$ . The value of *b* is a signed quantity in two's complement notation,  $-128 \leq b < 128$ . This command changes the current *w* spacing and moves right by *b*.
- w2* 149 *b*[2]. Same as *w1*, but *b* is two bytes long,  $-32768 \leq b < 32768$ .
- w3* 150 *b*[3]. Same as *w1*, but *b* is three bytes long,  $-2^{23} \leq b < 2^{23}$ .
- w4* 151 *b*[4]. Same as *w1*, but *b* is four bytes long,  $-2^{31} \leq b < 2^{31}$ .
- x0* 152. Set  $h \leftarrow h + x$ ; i.e., move right *x* units. The '*x*' commands are like the '*w*' commands except that they involve *x* instead of *w*.
- x1* 153 *b*[1]. Set  $x \leftarrow b$  and  $h \leftarrow h + b$ . The value of *b* is a signed quantity in two's complement notation,  $-128 \leq b < 128$ . This command changes the current *x* spacing and moves right by *b*.
- x2* 154 *b*[2]. Same as *x1*, but *b* is two bytes long,  $-32768 \leq b < 32768$ .
- x3* 155 *b*[3]. Same as *x1*, but *b* is three bytes long,  $-2^{23} \leq b < 2^{23}$ .
- x4* 156 *b*[4]. Same as *x1*, but *b* is four bytes long,  $-2^{31} \leq b < 2^{31}$ .
- down1* 157 *a*[1]. Set  $v \leftarrow v + a$ , i.e., move down *a* units. The parameter is a signed number in two's complement notation,  $-128 \leq a < 128$ ; if *a* < 0, the reference point moves up.
- down2* 158 *a*[2]. Same as *down1*, except that *a* is a two-byte quantity in the range  $-32768 \leq a < 32768$ .
- down3* 159 *a*[3]. Same as *down1*, except that *a* is a three-byte quantity in the range  $-2^{23} \leq a < 2^{23}$ .
- down4* 160 *a*[4]. Same as *down1*, except that *a* is a four-byte quantity in the range  $-2^{31} \leq a < 2^{31}$ .
- y0* 161. Set  $v \leftarrow v + y$ ; i.e., move down *y* units. With luck, this parameterless command will usually suffice, because the same kind of motion will occur several times in succession; the following commands explain how *y* gets particular values.
- y1* 162 *a*[1]. Set  $y \leftarrow a$  and  $v \leftarrow v + a$ . The value of *a* is a signed quantity in two's complement notation,  $-128 \leq a < 128$ . This command changes the current *y* spacing and moves down by *a*.
- y2* 163 *a*[2]. Same as *y1*, but *a* is two bytes long,  $-32768 \leq a < 32768$ .
- y3* 164 *a*[3]. Same as *y1*, but *a* is three bytes long,  $-2^{23} \leq a < 2^{23}$ .
- y4* 165 *a*[4]. Same as *y1*, but *a* is four bytes long,  $-2^{31} \leq a < 2^{31}$ .
- z0* 166. Set  $v \leftarrow v + z$ ; i.e., move down *z* units. The '*z*' commands are like the '*y*' commands except that they involve *z* instead of *y*.
- z1* 167 *a*[1]. Set  $z \leftarrow a$  and  $v \leftarrow v + a$ . The value of *a* is a signed quantity in two's complement notation,  $-128 \leq a < 128$ . This command changes the current *z* spacing and moves down by *a*.
- z2* 168 *a*[2]. Same as *z1*, but *a* is two bytes long,  $-32768 \leq a < 32768$ .
- z3* 169 *a*[3]. Same as *z1*, but *a* is three bytes long,  $-2^{23} \leq a < 2^{23}$ .
- z4* 170 *a*[4]. Same as *z1*, but *a* is four bytes long,  $-2^{31} \leq a < 2^{31}$ .
- fnt\_num\_0* 171. Set  $f \leftarrow 0$ . Font 0 must previously have been defined by a *fnt\_def* instruction, as explained below.
- fnt\_num\_1* through *fnt\_num\_63* (opcodes 172 to 234). Set  $f \leftarrow 1, \dots, f \leftarrow 63$ , respectively.
- fnt1* 235 *k*[1]. Set  $f \leftarrow k$ . T<sub>E</sub>X82 uses this command for font numbers in the range  $64 \leq k < 256$ .
- fnt2* 236 *k*[2]. Same as *fnt1*, except that *k* is two bytes long, so it is in the range  $0 \leq k < 65536$ . T<sub>E</sub>X82 never generates this command, but large font numbers may prove useful for specifications of color or texture, or they may be used for special fonts that have fixed numbers in some external coding scheme.

- fnt3* 237 *k*[3]. Same as *fnt1*, except that *k* is three bytes long, so it can be as large as  $2^{24} - 1$ .
- fnt4* 238 *k*[4]. Same as *fnt1*, except that *k* is four bytes long; this is for the really big font numbers (and for the negative ones).
- xxx1* 239 *k*[1] *x*[*k*]. This command is undefined in general; it functions as a (*k* + 2)-byte *nop* unless special DVI-reading programs are being used. T<sub>E</sub>X82 generates *xxx1* when a short enough `\special` appears, setting *k* to the number of bytes being sent. It is recommended that *x* be a string having the form of a keyword followed by possible parameters relevant to that keyword.
- xxx2* 240 *k*[2] *x*[*k*]. Like *xxx1*, but  $0 \leq k < 65536$ .
- xxx3* 241 *k*[3] *x*[*k*]. Like *xxx1*, but  $0 \leq k < 2^{24}$ .
- xxx4* 242 *k*[4] *x*[*k*]. Like *xxx1*, but *k* can be ridiculously large. T<sub>E</sub>X82 uses *xxx4* when sending a string of length 256 or more.
- fnt\_def1* 243 *k*[1] *c*[4] *s*[4] *d*[4] *a*[1] *l*[1] *n*[*a* + *l*]. Define font *k*, where  $0 \leq k < 256$ ; font definitions will be explained shortly.
- fnt\_def2* 244 *k*[2] *c*[4] *s*[4] *d*[4] *a*[1] *l*[1] *n*[*a* + *l*]. Define font *k*, where  $0 \leq k < 65536$ .
- fnt\_def3* 245 *k*[3] *c*[4] *s*[4] *d*[4] *a*[1] *l*[1] *n*[*a* + *l*]. Define font *k*, where  $0 \leq k < 2^{24}$ .
- fnt\_def4* 246 *k*[4] *c*[4] *s*[4] *d*[4] *a*[1] *l*[1] *n*[*a* + *l*]. Define font *k*, where  $-2^{31} \leq k < 2^{31}$ .
- pre* 247 *i*[1] *num*[4] *den*[4] *mag*[4] *k*[1] *x*[*k*]. Beginning of the preamble; this must come at the very beginning of the file. Parameters *i*, *num*, *den*, *mag*, *k*, and *x* are explained below.
- post* 248. Beginning of the postamble, see below.
- post\_post* 249. Ending of the postamble, see below.
- Commands 250–255 are undefined at the present time.

```

597. define set_char_0 = 0 { typeset character 0 and move right }

```

**598.** The preamble contains basic information about the file as a whole. As stated above, there are six parameters:

$$i[1] \text{ num}[4] \text{ den}[4] \text{ mag}[4] \text{ k}[1] \text{ x}[k].$$

The *i* byte identifies DVI format; currently this byte is always set to 2. (The value *i* = 3 is currently used for an extended format that allows a mixture of right-to-left and left-to-right typesetting. Some day we will set *i* = 4, when DVI format makes another incompatible change—perhaps in the year 2048.)

The next two parameters, *num* and *den*, are positive integers that define the units of measurement; they are the numerator and denominator of a fraction by which all dimensions in the DVI file could be multiplied in order to get lengths in units of  $10^{-7}$  meters. Since  $7227\text{pt} = 254\text{cm}$ , and since T<sub>E</sub>X works with scaled points where there are  $2^{16}$  sp in a point, T<sub>E</sub>X sets  $\text{num}/\text{den} = (254 \cdot 10^5)/(7227 \cdot 2^{16}) = 25400000/473628672$ .

The *mag* parameter is what T<sub>E</sub>X calls `\mag`, i.e., 1000 times the desired magnification. The actual fraction by which dimensions are multiplied is therefore  $\text{mag} \cdot \text{num}/1000\text{den}$ . Note that if a T<sub>E</sub>X source document does not call for any ‘true’ dimensions, and if you change it only by specifying a different `\mag` setting, the DVI file that T<sub>E</sub>X creates will be completely unchanged except for the value of *mag* in the preamble and postamble. (Fancy DVI-reading programs allow users to override the *mag* setting when a DVI file is being printed.)

Finally, *k* and *x* allow the DVI writer to include a comment, which is not interpreted further. The length of comment *x* is *k*, where  $0 \leq k < 256$ .

```

define id_byte = 2 { identifies the kind of DVI files described here }
define ex_id_byte = 3 { identifies the kind of extended DVI files }

```

**599.** Font definitions for a given font number  $k$  contain further parameters

$$c[4] s[4] d[4] a[1] l[1] n[a + l].$$

The four-byte value  $c$  is the check sum that T<sub>E</sub>X found in the TFM file for this font;  $c$  should match the check sum of the font found by programs that read this DVI file.

Parameter  $s$  contains a fixed-point scale factor that is applied to the character widths in font  $k$ ; font dimensions in TFM files and other font files are relative to this quantity, which is called the “at size” elsewhere in this documentation. The value of  $s$  is always positive and less than  $2^{27}$ . It is given in the same units as the other DVI dimensions, i.e., in sp when T<sub>E</sub>X82 has made the file. Parameter  $d$  is similar to  $s$ ; it is the “design size,” and (like  $s$ ) it is given in DVI units. Thus, font  $k$  is to be used at  $mag \cdot s/1000d$  times its normal size.

The remaining part of a font definition gives the external name of the font, which is an ASCII string of length  $a + l$ . The number  $a$  is the length of the “area” or directory, and  $l$  is the length of the font name itself; the standard local system font area is supposed to be used when  $a = 0$ . The  $n$  field contains the area in its first  $a$  bytes.

Font definitions must appear before the first use of a particular font number. Once font  $k$  is defined, it must not be defined again; however, we shall see below that font definitions appear in the postamble as well as in the pages, so in this sense each font number is defined exactly twice, if at all. Like *nop* commands, font definitions can appear before the first *bop*, or between an *eop* and a *bop*.

**600.** Sometimes it is desirable to make horizontal or vertical rules line up precisely with certain features in characters of a font. It is possible to guarantee the correct matching between DVI output and the characters generated by METAFONT by adhering to the following principles: (1) The METAFONT characters should be positioned so that a bottom edge or left edge that is supposed to line up with the bottom or left edge of a rule appears at the reference point, i.e., in row 0 and column 0 of the METAFONT raster. This ensures that the position of the rule will not be rounded differently when the pixel size is not a perfect multiple of the units of measurement in the DVI file. (2) A typeset rule of height  $a > 0$  and width  $b > 0$  should be equivalent to a METAFONT-generated character having black pixels in precisely those raster positions whose METAFONT coordinates satisfy  $0 \leq x < ab$  and  $0 \leq y < \alpha a$ , where  $\alpha$  is the number of pixels per DVI unit.

**601.** The last page in a DVI file is followed by ‘*post*’; this command introduces the postamble, which summarizes important facts that T<sub>E</sub>X has accumulated about the file, making it possible to print subsets of the data with reasonable efficiency. The postamble has the form

$$\begin{aligned} &post\ p[4]\ num[4]\ den[4]\ mag[4]\ l[4]\ u[4]\ s[2]\ t[2] \\ &\langle \text{font definitions} \rangle \\ &post\_post\ q[4]\ i[1]\ 223's[\geq 4] \end{aligned}$$

Here  $p$  is a pointer to the final *bop* in the file. The next three parameters,  $num$ ,  $den$ , and  $mag$ , are duplicates of the quantities that appeared in the preamble.

Parameters  $l$  and  $u$  give respectively the height-plus-depth of the tallest page and the width of the widest page, in the same units as other dimensions of the file. These numbers might be used by a DVI-reading program to position individual “pages” on large sheets of film or paper; however, the standard convention for output on normal size paper is to position each page so that the upper left-hand corner is exactly one inch from the left and the top. Experience has shown that it is unwise to design DVI-to-printer software that attempts cleverly to center the output; a fixed position of the upper left corner is easiest for users to understand and to work with. Therefore  $l$  and  $u$  are often ignored.

Parameter  $s$  is the maximum stack depth (i.e., the largest excess of *push* commands over *pop* commands) needed to process this file. Then comes  $t$ , the total number of pages (*bop* commands) present.

The postamble continues with font definitions, which are any number of *font.def* commands as described above, possibly interspersed with *nop* commands. Each font number that is used in the DVI file must be defined exactly twice: Once before it is first selected by a *font* command, and once in the postamble.

**602.** The last part of the postamble, following the *post\_post* byte that signifies the end of the font definitions, contains *q*, a pointer to the *post* command that started the postamble. An identification byte, *i*, comes next; this equals 2 or 3. If not used pT<sub>E</sub>Xprimitives then the identification byte equals 2, otherwise this is set to 3.

The *i* byte is followed by four or more bytes that are all equal to the decimal number 223 (i.e., '337 in octal). T<sub>E</sub>X puts out four to seven of these trailing bytes, until the total length of the file is a multiple of four bytes, since this works out best on machines that pack four bytes per word; but any number of 223's is allowed, as long as there are at least four of them. In effect, 223 is a sort of signature that is added at the very end.

This curious way to finish off a DVI file makes it feasible for DVI-reading programs to find the postamble first, on most computers, even though T<sub>E</sub>X wants to write the postamble last. Most operating systems permit random access to individual words or bytes of a file, so the DVI reader can start at the end and skip backwards over the 223's until finding the identification byte. Then it can back up four bytes, read *q*, and move to byte *q* of the file. This byte should, of course, contain the value 248 (*post*); now the postamble can be read, so the DVI reader can discover all the information needed for typesetting the pages. Note that it is also possible to skip through the DVI file at reasonably high speed to locate a particular page, if that proves desirable. This saves a lot of time, since DVI files used in production jobs tend to be large.

Unfortunately, however, standard Pascal does not include the ability to access a random position in a file, or even to determine the length of a file. Almost all systems nowadays provide the necessary capabilities, so DVI format has been designed to work most efficiently with modern operating systems. But if DVI files have to be processed under the restrictions of standard Pascal, one can simply read them from front to back, since the necessary header information is present in the preamble and in the font definitions. (The *l* and *u* and *s* and *t* parameters, which appear only in the postamble, are “frills” that are handy but not absolutely necessary.)

**603. Shipping pages out.** After considering T<sub>E</sub>X’s eyes and stomach, we come now to the bowels.

The *ship\_out* procedure is given a pointer to a box; its mission is to describe that box in DVI form, outputting a “page” to *dvi\_file*. The DVI coordinates  $(h, v) = (0, 0)$  should correspond to the upper left corner of the box being shipped.

Since boxes can be inside of boxes inside of boxes, the main work of *ship\_out* is done by two mutually recursive routines, *hlist\_out* and *vlist\_out*, which traverse the hlists and vlists inside of horizontal and vertical boxes.

As individual pages are being processed, we need to accumulate information about the entire set of pages, since such statistics must be reported in the postamble. The global variables *total\_pages*, *max\_v*, *max\_h*, *max\_push*, and *last\_bop* are used to record this information.

The variable *doing\_leaders* is *true* while leaders are being output. The variable *dead\_cycles* contains the number of times an output routine has been initiated since the last *ship\_out*.

A few additional global variables are also defined here for use in *vlist\_out* and *hlist\_out*. They could have been local variables, but that would waste stack space when boxes are deeply nested, since the values of these variables are not needed during recursive calls.

```

⟨Global variables 13⟩ +≡
total_pages: integer; { the number of pages that have been shipped out }
max_v: scaled; { maximum height-plus-depth of pages shipped so far }
max_h: scaled; { maximum width of pages shipped so far }
max_push: integer; { deepest nesting of push commands encountered so far }
last_bop: integer; { location of previous bop in the DVI output }
dead_cycles: integer; { recent outputs that didn't ship anything out }
doing_leaders: boolean; { are we inside a leader box? }

{ character and font in current char_node }
c: quarterword;
f: internal_font_number;
dir_used: boolean; { Is this dvi extended? }
rule_ht, rule_dp, rule_wd: scaled; { size of current rule being output }
g: pointer; { current glue specification }
lq, lr: integer; { quantities used in calculations for leaders }

```

```

604. ⟨Set initial values of key variables 21⟩ +≡
total_pages ← 0; max_v ← 0; max_h ← 0; max_push ← 0; last_bop ← -1; doing_leaders ← false;
dead_cycles ← 0; cur_s ← -1; dir_used ← false;

```

**605.** The DVI bytes are output to a buffer instead of being written directly to the output file. This makes it possible to reduce the overhead of subroutine calls, thereby measurably speeding up the computation, since output of DVI bytes is part of T<sub>E</sub>X’s inner loop. And it has another advantage as well, since we can change instructions in the buffer in order to make the output more compact. For example, a ‘*down2*’ command can be changed to a ‘*y2*’, thereby making a subsequent ‘*y0*’ command possible, saving two bytes.

The output buffer is divided into two parts of equal size; the bytes found in *dvi\_buf*[0 .. *half\_buf* - 1] constitute the first half, and those in *dvi\_buf*[*half\_buf* .. *dvi\_buf\_size* - 1] constitute the second. The global variable *dvi\_ptr* points to the position that will receive the next output byte. When *dvi\_ptr* reaches *dvi\_limit*, which is always equal to one of the two values *half\_buf* or *dvi\_buf\_size*, the half buffer that is about to be invaded next is sent to the output and *dvi\_limit* is changed to its other value. Thus, there is always at least a half buffer’s worth of information present, except at the very beginning of the job.

Bytes of the DVI file are numbered sequentially starting with 0; the next byte to be generated will be number *dvi\_offset* + *dvi\_ptr*. A byte is present in the buffer only if its number is  $\geq$  *dvi\_gone*.

```

⟨Types in the outer block 18⟩ +≡
dvi_index = 0 .. dvi_buf_size; { an index into the output buffer }

```

**606.** Some systems may find it more efficient to make *dvi\_buf* a **packed** array, since output of four bytes at once may be facilitated.

```

⟨Global variables 13⟩ +=
dvi_buf: ↑eight_bits; { buffer for DVI output }
half_buf: integer; { half of dvi_buf_size }
dvi_limit: integer; { end of the current half buffer }
dvi_ptr: integer; { the next available buffer address }
dvi_offset: integer; { dvi_buf_size times the number of times the output buffer has been fully emptied }
dvi_gone: integer; { the number of bytes already output to dvi_file }

```

**607.** Initially the buffer is all in one piece; we will output half of it only after it first fills up.

```

⟨Set initial values of key variables 21⟩ +=
half_buf ← dvi_buf_size div 2; dvi_limit ← dvi_buf_size; dvi_ptr ← 0; dvi_offset ← 0; dvi_gone ← 0;

```

**608.** The actual output of *dvi\_buf*[*a* .. *b*] to *dvi\_file* is performed by calling *write\_dvi*(*a*, *b*). For best results, this procedure should be optimized to run as fast as possible on each particular system, since it is part of TEX's inner loop. It is safe to assume that *a* and *b* + 1 will both be multiples of 4 when *write\_dvi*(*a*, *b*) is called; therefore it is possible on many machines to use efficient methods to pack four bytes per word and to output an array of words with one system call.

In C, we use a macro to call *fwrite* or *write* directly, writing all the bytes in one shot. Much better even than writing four bytes at a time.

**609.** To put a byte in the buffer without paying the cost of invoking a procedure each time, we use the macro *dvi\_out*.

The length of *dvi\_file* should not exceed "7FFFFFFF"; we set *cur\_s* ← -2 to prevent further DVI output causing infinite recursion.

```

define dvi_out(#) ≡ begin dvi_buf[dvi_ptr] ← #; incr(dvi_ptr);
if dvi_ptr = dvi_limit then dvi_swap;
end

```

```

procedure dvi_swap; { outputs half of the buffer }
begin if dvi_ptr > ("7FFFFFFF - dvi_offset") then
begin cur_s ← -2; fatal_error("dvi_length_exceeds_" "7FFFFFFF");
end;
if dvi_limit = dvi_buf_size then
begin write_dvi(0, half_buf - 1); dvi_limit ← half_buf; dvi_offset ← dvi_offset + dvi_buf_size;
dvi_ptr ← 0;
end
else begin write_dvi(half_buf, dvi_buf_size - 1); dvi_limit ← dvi_buf_size;
end;
dvi_gone ← dvi_gone + half_buf;
end;

```

**610.** Here is how we clean out the buffer when TEX is all through; *dvi\_ptr* will be a multiple of 4.

```

⟨Empty the last bytes out of dvi_buf 610⟩ ≡
if dvi_limit = half_buf then write_dvi(half_buf, dvi_buf_size - 1);
if dvi_ptr > ("7FFFFFFF - dvi_offset") then
begin cur_s ← -2; fatal_error("dvi_length_exceeds_" "7FFFFFFF");
end;
if dvi_ptr > 0 then write_dvi(0, dvi_ptr - 1)

```

This code is used in section 653.

**611.** The *dvi\_four* procedure outputs four bytes in two's complement notation, without risking arithmetic overflow.

```

procedure dvi_four(x : integer);
  begin if x ≥ 0 then dvi_out(x div '100000000)
  else begin x ← x + '10000000000; x ← x + '10000000000; dvi_out((x div '100000000) + 128);
    end;
  x ← x mod '100000000; dvi_out(x div '200000); x ← x mod '200000; dvi_out(x div '400);
  dvi_out(x mod '400);
end;

```

**612.** A mild optimization of the output is performed by the *dvi\_pop* routine, which issues a *pop* unless it is possible to cancel a 'push pop' pair. The parameter to *dvi\_pop* is the byte address following the old *push* that matches the new *pop*.

```

procedure dvi_pop(l : integer);
  begin if (l = dvi_offset + dvi_ptr) ∧ (dvi_ptr > 0) then decr(dvi_ptr)
  else dvi_out(pop);
end;

```

**613.** Here's a procedure that outputs a font definition. Since T<sub>E</sub>X82 uses at most 256 different fonts per job, *font\_def1* is always used as the command code.

```

procedure dvi_font_def(f : internal_font_number);
  var k: pool_pointer; { index into str_pool }
  begin if f ≤ 256 + font_base then
    begin dvi_out(font_def1); dvi_out(f - font_base - 1);
    end
  else begin dvi_out(font_def1 + 1); dvi_out((f - font_base - 1) div '400);
    dvi_out((f - font_base - 1) mod '400);
    end;
  dvi_out(qo(font_check[f].b0)); dvi_out(qo(font_check[f].b1)); dvi_out(qo(font_check[f].b2));
  dvi_out(qo(font_check[f].b3));
  dvi_four(font_size[f]); dvi_four(font_dsize[f]);
  dvi_out(length(font_area[f])); dvi_out(length(font_name[f]));
  ⟨Output the font name whose internal number is f 614⟩;
end;

```

**614.** ⟨Output the font name whose internal number is *f* 614⟩ ≡

```

for k ← str_start[font_area[f]] to str_start[font_area[f] + 1] - 1 do dvi_out(so(str_pool[k]));
for k ← str_start[font_name[f]] to str_start[font_name[f] + 1] - 1 do dvi_out(so(str_pool[k]))

```

This code is used in section 613.

**615.** Versions of TEX intended for small computers might well choose to omit the ideas in the next few parts of this program, since it is not really necessary to optimize the DVI code by making use of the  $w0$ ,  $x0$ ,  $y0$ , and  $z0$  commands. Furthermore, the algorithm that we are about to describe does not pretend to give an optimum reduction in the length of the DVI code; after all, speed is more important than compactness. But the method is surprisingly effective, and it takes comparatively little time.

We can best understand the basic idea by first considering a simpler problem that has the same essential characteristics. Given a sequence of digits, say 3 1 4 1 5 9 2 6 5 3 5 8 9, we want to assign subscripts  $d$ ,  $y$ , or  $z$  to each digit so as to maximize the number of “ $y$ -hits” and “ $z$ -hits”; a  $y$ -hit is an instance of two appearances of the same digit with the subscript  $y$ , where no  $y$ 's intervene between the two appearances, and a  $z$ -hit is defined similarly. For example, the sequence above could be decorated with subscripts as follows:

$$3_z 1_y 4_d 1_y 5_y 9_d 2_d 6_d 5_y 3_z 5_y 8_d 9_d.$$

There are three  $y$ -hits ( $1_y \dots 1_y$  and  $5_y \dots 5_y \dots 5_y$ ) and one  $z$ -hit ( $3_z \dots 3_z$ ); there are no  $d$ -hits, since the two appearances of  $9_d$  have  $d$ 's between them, but we don't count  $d$ -hits so it doesn't matter how many there are. These subscripts are analogous to the DVI commands called *down*,  $y$ , and  $z$ , and the digits are analogous to different amounts of vertical motion; a  $y$ -hit or  $z$ -hit corresponds to the opportunity to use the one-byte commands  $y0$  or  $z0$  in a DVI file.

TEX's method of assigning subscripts works like this: Append a new digit, say  $\delta$ , to the right of the sequence. Now look back through the sequence until one of the following things happens: (a) You see  $\delta_y$  or  $\delta_z$ , and this was the first time you encountered a  $y$  or  $z$  subscript, respectively. Then assign  $y$  or  $z$  to the new  $\delta$ ; you have scored a hit. (b) You see  $\delta_d$ , and no  $y$  subscripts have been encountered so far during this search. Then change the previous  $\delta_d$  to  $\delta_y$  (this corresponds to changing a command in the output buffer), and assign  $y$  to the new  $\delta$ ; it's another hit. (c) You see  $\delta_d$ , and a  $y$  subscript has been seen but not a  $z$ . Change the previous  $\delta_d$  to  $\delta_z$  and assign  $z$  to the new  $\delta$ . (d) You encounter both  $y$  and  $z$  subscripts before encountering a suitable  $\delta$ , or you scan all the way to the front of the sequence. Assign  $d$  to the new  $\delta$ ; this assignment may be changed later.

The subscripts  $3_z 1_y 4_d \dots$  in the example above were, in fact, produced by this procedure, as the reader can verify. (Go ahead and try it.)

**616.** In order to implement such an idea, TEX maintains a stack of pointers to the *down*,  $y$ , and  $z$  commands that have been generated for the current page. And there is a similar stack for *right*,  $w$ , and  $x$  commands. These stacks are called the down stack and right stack, and their top elements are maintained in the variables *down\_ptr* and *right\_ptr*.

Each entry in these stacks contains four fields: The *width* field is the amount of motion down or to the right; the *location* field is the byte number of the DVI command in question (including the appropriate *dvi\_offset*); the *link* field points to the next item below this one on the stack; and the *info* field encodes the options for possible change in the DVI command.

```
define movement_node_size = 3 { number of words per entry in the down and right stacks }
define location(#) ≡ mem[# + 2].int { DVI byte number for a movement command }
```

```
< Global variables 13 > +≡
```

```
down_ptr, right_ptr: pointer; { heads of the down and right stacks }
```

**617.** < Set initial values of key variables 21 > +≡

```
down_ptr ← null; right_ptr ← null;
```

**618.** Here is a subroutine that produces a DVI command for some specified downward or rightward motion. It has two parameters:  $w$  is the amount of motion, and  $o$  is either *down1* or *right1*. We use the fact that the command codes have convenient arithmetic properties:  $y1 - \text{down1} = w1 - \text{right1}$  and  $z1 - \text{down1} = x1 - \text{right1}$ .

```

procedure movement( $w$  : scaled;  $o$  : eight_bits);
  label exit, found, not_found, 2, 1;
  var mstate: small_number; { have we seen a  $y$  or  $z$ ? }
       $p, q$ : pointer; { current and top nodes on the stack }
       $k$ : integer; { index into dvi_buf, modulo dvi_buf_size }
  begin  $q \leftarrow \text{get\_node}(\text{movement\_node\_size})$ ; { new node for the top of the stack }
  width( $q$ )  $\leftarrow w$ ; location( $q$ )  $\leftarrow \text{dvi\_offset} + \text{dvi\_ptr}$ ;
  if  $o = \text{down1}$  then
    begin link( $q$ )  $\leftarrow \text{down\_ptr}$ ; down_ptr  $\leftarrow q$ ;
    end
  else begin link( $q$ )  $\leftarrow \text{right\_ptr}$ ; right_ptr  $\leftarrow q$ ;
  end;
  <Look at the other stack entries until deciding what sort of DVI command to generate; goto found if
  node  $p$  is a “hit” 622>;
  <Generate a down or right command for  $w$  and return 621>;
found: <Generate a  $y0$  or  $z0$  command in order to reuse a previous appearance of  $w$  620>;
exit: end;

```

**619.** The *info* fields in the entries of the down stack or the right stack have six possible settings: *y\_here* or *z\_here* mean that the DVI command refers to  $y$  or  $z$ , respectively (or to  $w$  or  $x$ , in the case of horizontal motion); *yz\_OK* means that the DVI command is *down* (or *right*) but can be changed to either  $y$  or  $z$  (or to either  $w$  or  $x$ ); *y\_OK* means that it is *down* and can be changed to  $y$  but not  $z$ ; *z\_OK* is similar; and *d\_fixed* means it must stay *down*.

The four settings *yz\_OK*, *y\_OK*, *z\_OK*, *d\_fixed* would not need to be distinguished from each other if we were simply solving the digit-subscripting problem mentioned above. But in T<sub>E</sub>X’s case there is a complication because of the nested structure of *push* and *pop* commands. Suppose we add parentheses to the digit-subscripting problem, redefining hits so that  $\delta_y \dots \delta_y$  is a hit if all  $y$ ’s between the  $\delta$ ’s are enclosed in properly nested parentheses, and if the parenthesis level of the right-hand  $\delta_y$  is deeper than or equal to that of the left-hand one. Thus, ‘(’ and ‘)’ correspond to ‘*push*’ and ‘*pop*’. Now if we want to assign a subscript to the final 1 in the sequence

$$2_y 7_d 1_d (8_z 2_y 8_z) 1$$

we cannot change the previous  $1_d$  to  $1_y$ , since that would invalidate the  $2_y \dots 2_y$  hit. But we can change it to  $1_z$ , scoring a hit since the intervening  $8_z$ ’s are enclosed in parentheses.

The program below removes movement nodes that are introduced after a *push*, before it outputs the corresponding *pop*.

```

define  $y\_here = 1$  { info when the movement entry points to a  $y$  command }
define  $z\_here = 2$  { info when the movement entry points to a  $z$  command }
define  $yz\_OK = 3$  { info corresponding to an unconstrained down command }
define  $y\_OK = 4$  { info corresponding to a down that can’t become a  $z$  }
define  $z\_OK = 5$  { info corresponding to a down that can’t become a  $y$  }
define  $d\_fixed = 6$  { info corresponding to a down that can’t change }

```

**620.** When the *movement* procedure gets to the label *found*, the value of *info(p)* will be either *y.here* or *z.here*. If it is, say, *y.here*, the procedure generates a *y0* command (or a *w0* command), and marks all *info* fields between *q* and *p* so that *y* is not OK in that range.

⟨Generate a *y0* or *z0* command in order to reuse a previous appearance of *w* 620⟩ ≡

```

info(q) ← info(p);
if info(q) = y.here then
  begin dvi_out(o + y0 - down1); { y0 or w0 }
  while link(q) ≠ p do
    begin q ← link(q);
    case info(q) of
      yz_OK: info(q) ← z_OK;
      y_OK: info(q) ← d_fixed;
    othercases do_nothing
    endcases;
  end;
end
else begin dvi_out(o + z0 - down1); { z0 or x0 }
  while link(q) ≠ p do
    begin q ← link(q);
    case info(q) of
      yz_OK: info(q) ← y_OK;
      z_OK: info(q) ← d_fixed;
    othercases do_nothing
    endcases;
  end;
end

```

This code is used in section 618.

**621.** ⟨Generate a *down* or *right* command for *w* and **return** 621⟩ ≡

```

info(q) ← yz_OK;
if abs(w) ≥ '40000000 then
  begin dvi_out(o + 3); { down4 or right4 }
  dvi_four(w); return;
  end;
if abs(w) ≥ '100000 then
  begin dvi_out(o + 2); { down3 or right3 }
  if w < 0 then w ← w + '100000000;
  dvi_out(w div '200000); w ← w mod '200000; goto 2;
  end;
if abs(w) ≥ '200 then
  begin dvi_out(o + 1); { down2 or right2 }
  if w < 0 then w ← w + '200000;
  goto 2;
  end;
dvi_out(o); { down1 or right1 }
if w < 0 then w ← w + '400;
goto 1;
2: dvi_out(w div '400);
1: dvi_out(w mod '400); return

```

This code is used in section 618.

**622.** As we search through the stack, we are in one of three states, *y\_seen*, *z\_seen*, or *none\_seen*, depending on whether we have encountered *y\_here* or *z\_here* nodes. These states are encoded as multiples of 6, so that they can be added to the *info* fields for quick decision-making.

```

define none_seen = 0 { no y_here or z_here nodes have been encountered yet }
define y_seen = 6 { we have seen y_here but not z_here }
define z_seen = 12 { we have seen z_here but not y_here }

```

⟨ Look at the other stack entries until deciding what sort of DVI command to generate; **goto found** if node *p* is a “hit” 622 ⟩ ≡

```
p ← link(q); mstate ← none_seen;
```

```
while p ≠ null do
```

```
  begin if width(p) = w then ⟨ Consider a node with matching width; goto found if it’s a hit 623 ⟩
```

```
  else case mstate + info(p) of
```

```
    none_seen + y_here: mstate ← y_seen;
```

```
    none_seen + z_here: mstate ← z_seen;
```

```
    y_seen + z_here, z_seen + y_here: goto not_found;
```

```
    othercases do_nothing
```

```
  endcases;
```

```
  p ← link(p);
```

```
  end;
```

```
not_found:
```

This code is used in section 618.

**623.** We might find a valid hit in a *y* or *z* byte that is already gone from the buffer. But we can’t change bytes that are gone forever; “the moving finger writes, . . . .”

⟨ Consider a node with matching width; **goto found** if it’s a hit 623 ⟩ ≡

```
case mstate + info(p) of
```

```
  none_seen + yz_OK, none_seen + y_OK, z_seen + yz_OK, z_seen + y_OK:
```

```
    if location(p) < dvi_gone then goto not_found
```

```
    else ⟨ Change buffered instruction to y or w and goto found 624 ⟩;
```

```
  none_seen + z_OK, y_seen + yz_OK, y_seen + z_OK:
```

```
    if location(p) < dvi_gone then goto not_found
```

```
    else ⟨ Change buffered instruction to z or x and goto found 625 ⟩;
```

```
  none_seen + y_here, none_seen + z_here, y_seen + z_here, z_seen + y_here: goto found;
```

```
  othercases do_nothing
```

```
endcases
```

This code is used in section 622.

**624.** ⟨ Change buffered instruction to *y* or *w* and **goto found** 624 ⟩ ≡

```
begin k ← location(p) − dvi_offset;
```

```
if k < 0 then k ← k + dvi_buf_size;
```

```
dvi_buf[k] ← dvi_buf[k] + y1 − down1; info(p) ← y_here; goto found;
```

```
end
```

This code is used in section 623.

**625.** ⟨ Change buffered instruction to *z* or *x* and **goto found** 625 ⟩ ≡

```
begin k ← location(p) − dvi_offset;
```

```
if k < 0 then k ← k + dvi_buf_size;
```

```
dvi_buf[k] ← dvi_buf[k] + z1 − down1; info(p) ← z_here; goto found;
```

```
end
```

This code is used in section 623.

**626.** In case you are wondering when all the movement nodes are removed from TEX's memory, the answer is that they are recycled just before *hlist\_out* and *vlist\_out* finish outputting a box. This restores the down and right stacks to the state they were in before the box was output, except that some *info*'s may have become more restrictive.

```

procedure prune_movements(l : integer); { delete movement nodes with location  $\geq$  l }
  label done, exit;
  var p: pointer; { node being deleted }
  begin while down_ptr  $\neq$  null do
    begin if location(down_ptr) < l then goto done;
    p  $\leftarrow$  down_ptr; down_ptr  $\leftarrow$  link(p); free_node(p, movement_node_size);
    end;
  done: while right_ptr  $\neq$  null do
    begin if location(right_ptr) < l then return;
    p  $\leftarrow$  right_ptr; right_ptr  $\leftarrow$  link(p); free_node(p, movement_node_size);
    end;
  exit: end;

```

**627.** The actual distances by which we want to move might be computed as the sum of several separate movements. For example, there might be several glue nodes in succession, or we might want to move right by the width of some box plus some amount of glue. More importantly, the baselineskip distances are computed in terms of glue together with the depth and height of adjacent boxes, and we want the DVI file to lump these three quantities together into a single motion.

Therefore, TEX maintains two pairs of global variables: *dvi\_h* and *dvi\_v* are the *h* and *v* coordinates corresponding to the commands actually output to the DVI file, while *cur\_h* and *cur\_v* are the coordinates corresponding to the current state of the output routines. Coordinate changes will accumulate in *cur\_h* and *cur\_v* without being reflected in the output, until such a change becomes necessary or desirable; we can call the *movement* procedure whenever we want to make *dvi\_h* = *cur\_h* or *dvi\_v* = *cur\_v*.

The current font reflected in the DVI output is called *dvi\_f*; there is no need for a '*cur\_f*' variable.

The depth of nesting of *hlist\_out* and *vlist\_out* is called *cur\_s*; this is essentially the depth of *push* commands in the DVI output.

```

define synch_h  $\equiv$ 
  if cur_h  $\neq$  dvi_h then
    begin movement(cur_h - dvi_h, right1); dvi_h  $\leftarrow$  cur_h;
    end
define synch_v  $\equiv$ 
  if cur_v  $\neq$  dvi_v then
    begin movement(cur_v - dvi_v, down1); dvi_v  $\leftarrow$  cur_v;
    end

```

< Global variables 13 > + $\equiv$

*dvi\_h*, *dvi\_v*: scaled; { a DVI reader program thinks we are here }

*cur\_h*, *cur\_v*: scaled; { TEX thinks we are here }

*dvi\_f*: internal\_font\_number; { the current font }

*cur\_s*: integer; { current depth of output box nesting, initially -1 }

**628.**  $\langle$  Initialize variables as *ship\_out* begins 628  $\rangle \equiv$

    **end**;  
  **end**

This code is used in section 651.

**629.** When *hlist\_out* is called, its duty is to output the box represented by the *hlist\_node* pointed to by *temp\_ptr*. The reference point of that box has coordinates (*cur\_h*, *cur\_v*).

Similarly, when *vlist\_out* is called, its duty is to output the box represented by the *vlist\_node* pointed to by *temp\_ptr*. The reference point of that box has coordinates (*cur\_h*, *cur\_v*).

**procedure** *vlist\_out*; *forward*; { *hlist\_out* and *vlist\_out* are mutually recursive }

**630.** The recursive procedures *hlist\_out* and *vlist\_out* each have local variables *save\_h* and *save\_v* to hold the values of *dvi\_h* and *dvi\_v* just before entering a new level of recursion. In effect, the values of *save\_h* and *save\_v* on TEX's run-time stack correspond to the values of *h* and *v* that a DVI-reading program will push onto its coordinate stack.

```

**631.** We ought to give special care to the efficiency of one part of *hlist\_out*, since it belongs to T<sub>E</sub>X's inner loop. When a *char\_node* is encountered, we save a little time by processing several nodes in succession until reaching a non-*char\_node*. The program uses the fact that *set\_char\_0* = 0.

In MLT<sub>E</sub>X this part looks for the existence of a substitution definition for a character *c*, if *c* does not exist in the font, and create appropriate DVI commands. Former versions of MLT<sub>E</sub>X have spliced appropriate character, kern, and box nodes into the horizontal list. Because the user can change character substitutions or `\charsubdefmax` on the fly, we have to test a again for valid substitutions. (Additional it is necessary to be careful—if leaders are used the current hlist is normally traversed more than once!)

```

This code is used in section 636.

**638.** The calculations related to leaders require a bit of care. First, in the case of *a\_leaders* (aligned leaders), we want to move *cur\_h* to *left\_edge* plus the smallest multiple of *leader\_wd* for which the result is not less than the current value of *cur\_h*; i.e., *cur\_h* should become  $left\_edge + leader\_wd \times \lceil (cur\_h - left\_edge) / leader\_wd \rceil$ . The program here should work in all cases even though some implementations of Pascal give nonstandard results for the **div** operation when *cur\_h* is less than *left\_edge*.

In the case of *c\_leaders* (centered leaders), we want to increase *cur\_h* by half of the excess space not occupied by the leaders; and in the case of *x\_leaders* (expanded leaders) we increase *cur\_h* by  $1/(q+1)$  of this excess space, where *q* is the number of times the leader box will be replicated. Slight inaccuracies in the division might accumulate; half of this rounding error is placed at each end of the leaders.

```

⟨ Let cur_h be the position of the first box, and set leader_wd + lx to the spacing between corresponding
  parts of boxes 638 ⟩ ≡
if subtype(p) = a_leaders then
  begin save_h ← cur_h; cur_h ← left_edge + leader_wd * ((cur_h - left_edge) div leader_wd);
  if cur_h < save_h then cur_h ← cur_h + leader_wd;
  end
else begin lq ← rule_wd div leader_wd; { the number of box copies }
  lr ← rule_wd mod leader_wd; { the remaining space }
  if subtype(p) = c_leaders then cur_h ← cur_h + (lr div 2)
  else begin lx ← lr div (lq + 1); cur_h ← cur_h + ((lr - (lq - 1) * lx) div 2);
  end;
end

```

This code is used in section 637.

**639.** The ‘*synch*’ operations here are intended to decrease the number of bytes needed to specify horizontal and vertical motion in the DVI output.

```

⟨ Output a leader box at cur_h, then advance cur_h by leader_wd + lx 639 ⟩ ≡
begin cur_v ← base_line + disp + shift_amount(leader_box); synch_v; save_v ← dvi_v;
synch_h; save_h ← dvi_h; save_dir ← dvi_dir; temp_ptr ← leader_box;
outer_doing_leaders ← doing_leaders; doing_leaders ← true;
case type(leader_box) of
  hlist_node: hlist_out;
  vlist_node: vlist_out;
  dir_node: dir_out;
endcases; doing_leaders ← outer_doing_leaders; dvi_v ← save_v; dvi_h ← save_h; dvi_dir ← save_dir;
cur_v ← base_line; cur_h ← save_h + leader_wd + lx; cur_dir_hv ← save_dir;
end

```

This code is used in section 637.

**640.** The *vlist\_out* routine is similar to *hlist\_out*, but a bit simpler.

```

procedure vlist_out; { output a vlist_node box }
  label move_past, fin_rule, next_p;
  var left_edge: scaled; { the left coordinate for this box }
      top_edge: scaled; { the top coordinate for this box }
      save_h, save_v: scaled; { what dvi_h and dvi_v should pop to }
      this_box: pointer; { pointer to containing box }
      g_order: glue_ord; { applicable order of infinity for glue }
      g_sign: normal .. shrinking; { selects type of glue }
      p: pointer; { current position in the vlist }
      save_loc: integer; { DVI byte location upon entry }
      leader_box: pointer; { the leader box being replicated }
      leader_ht: scaled; { height of leader box being replicated }
      lx: scaled; { extra space between leader boxes }
      outer_doing_leaders: boolean; { were we doing leaders? }
      edge: scaled; { bottom boundary of leader space }
      glue_temp: real; { glue value before rounding }
      cur_glue: real; { glue seen so far }
      cur_g: scaled; { rounded equivalent of cur_glue times the glue ratio }
      save_dir: integer; { what dvi_dir should pop to }
  begin cur_g ← 0; cur_glue ← float_constant(0); this_box ← temp_ptr; g_order ← glue_order(this_box);
  g_sign ← glue_sign(this_box); p ← list_ptr(this_box); incr(cur_s);
  if cur_s > 0 then dvi_out(push);
  if cur_s > max_push then max_push ← cur_s;
  save_loc ← dvi_offset + dvi_ptr; synch_dir; left_edge ← cur_h; cur_v ← cur_v - height(this_box);
  top_edge ← cur_v;
  while p ≠ null do { Output node p for vlist_out and move to the next node, maintaining the condition
      cur_h = left_edge 641 };
  prune_movements(save_loc);
  if cur_s > 0 then dvi_pop(save_loc);
  decr(cur_s);
  end;

```

```

641. { Output node p for vlist_out and move to the next node, maintaining the condition
      cur_h = left_edge 641 } ≡
  begin if is_char_node(p) then confusion("vlistout")
  else { Output the non-char_node p for vlist_out 642 };
  next_p: p ← link(p);
  end

```

This code is used in section 640.

```

642.  ⟨Output the non-char_node p for vlist_out 642⟩ ≡
  begin case type(p) of
    hlist_node, vlist_node, dir_node: ⟨Output a box in a vlist 643⟩;
    rule_node: begin rule_ht ← height(p); rule_dp ← depth(p); rule_wd ← width(p); goto fin_rule;
    end;
    whatsit_node: ⟨Output the whatsit node p in a vlist 1379⟩;
    glue_node: ⟨Move down or output leaders 645⟩;
    kern_node: cur_v ← cur_v + width(p);

    decr(font_ptr);
  end

```

This code is used in section 653.

**655. Packaging.** We're essentially done with the parts of T<sub>E</sub>X that are concerned with the input (*get\_next*) and the output (*ship\_out*). So it's time to get heavily into the remaining part, which does the real work of typesetting.

After lists are constructed, T<sub>E</sub>X wraps them up and puts them into boxes. Two major subroutines are given the responsibility for this task: *hpack* applies to horizontal lists (hlists) and *vpack* applies to vertical lists (vlists). The main duty of *hpack* and *vpack* is to compute the dimensions of the resulting boxes, and to adjust the glue if one of those dimensions is pre-specified. The computed sizes normally enclose all of the material inside the new box; but some items may stick out if negative glue is used, if the box is overfull, or if a  $\vbox$  includes other boxes that have been shifted left.

The subroutine call *hpack*(*p*, *w*, *m*) returns a pointer to an *hlist\_node* for a box containing the hlist that starts at *p*. Parameter *w* specifies a width; and parameter *m* is either 'exactly' or 'additional'. Thus, *hpack*(*p*, *w*, *exactly*) produces a box whose width is exactly *w*, while *hpack*(*p*, *w*, *additional*) yields a box whose width is the natural width plus *w*. It is convenient to define a macro called 'natural' to cover the most common case, so that we can say *hpack*(*p*, *natural*) to get a box that has the natural width of list *p*.

Similarly, *vpack*(*p*, *w*, *m*) returns a pointer to a *vlist\_node* for a box containing the vlist that starts at *p*. In this case *w* represents a height instead of a width; the parameter *m* is interpreted as in *hpack*.

```
define exactly = 0 { a box dimension is pre-specified }
define additional = 1 { a box dimension is increased from the natural one }
define natural ≡ 0, additional { shorthand for parameters to hpack and vpack }
```

**656.** The parameters to *hpack* and *vpack* correspond to T<sub>E</sub>X's primitives like ' $\hbox to 300pt$ ', ' $\hbox spread 10pt$ '; note that ' $\hbox$ ' with no dimension following it is equivalent to ' $\hbox spread 0pt$ '. The *scan\_spec* subroutine scans such constructions in the user's input, including the mandatory left brace that follows them, and it puts the specification onto *save\_stack* so that the desired box can later be obtained by executing the following code:

```
save_ptr ← save_ptr - 2;
hpack(p, saved(1), saved(0)).
```

Special care is necessary to ensure that the special *save\_stack* codes are placed just below the new group code, because scanning can change *save\_stack* when  $\cscname$  appears.

```
procedure scan_spec(c : group_code; three_codes : boolean); { scans a box specification and left brace }
  label found;
  var s : integer; { temporarily saved value }
  spec_code : exactly .. additional;
  begin if three_codes then s ← saved(0);
  if scan_keyword("to") then spec_code ← exactly
  else if scan_keyword("spread") then spec_code ← additional
  else begin spec_code ← additional; cur_val ← 0; goto found;
  end;
  scan_normal_dimen;
  found : if three_codes then
    begin saved(0) ← s; incr(save_ptr);
    end;
  saved(0) ← spec_code; saved(1) ← cur_val; save_ptr ← save_ptr + 2; new_save_level(c); scan_left_brace;
  end;
```

**657.** To figure out the glue setting, *hpack* and *vpack* determine how much stretchability and shrinkability are present, considering all four orders of infinity. The highest order of infinity that has a nonzero coefficient is then used as if no other orders were present.

For example, suppose that the given list contains six glue nodes with the respective stretchabilities 3pt, 8fil, 5fil, 6pt, -3fil, -8fil. Then the total is essentially 2fil; and if a total additional space of 6pt is to be achieved by stretching, the actual amounts of stretch will be 0pt, 0pt, 15pt, 0pt, -9pt, and 0pt, since only ‘fil’ glue will be considered. (The ‘fil’ glue is therefore not really stretching infinitely with respect to ‘fil’; nobody would actually want that to happen.)

The arrays *total\_stretch* and *total\_shrink* are used to determine how much glue of each kind is present. A global variable *last\_badness* is used to implement `\badness`.

```
⟨ Global variables 13 ⟩ +≡
total_stretch, total_shrink: array [glue_ord] of scaled; { glue found by hpack or vpack }
last_badness: integer; { badness of the most recently packaged box }
```

**658.** If the global variable *adjust\_tail* is non-null, the *hpack* routine also removes all occurrences of *ins\_node*, *mark\_node*, and *adjust\_node* items and appends the resulting material onto the list that ends at location *adjust\_tail*.

```
⟨ Global variables 13 ⟩ +≡
adjust_tail: pointer; { tail of adjustment list }
last_disp: scaled; { displacement at end of list }
cur_kanji_skip: pointer;
cur_xkanji_skip: pointer;
```

```
659. ⟨ Set initial values of key variables 21 ⟩ +≡
adjust_tail ← null; last_badness ← 0; cur_kanji_skip ← zero_glue; cur_xkanji_skip ← zero_glue;
{ koko incr(glue_ref_count(cur_kanji_skip)); incr(glue_ref_count(cur_xkanji_skip)); }
```

**660.** Here now is *hpack*, which contains few if any surprises.

```

function hpack(p : pointer; w : scaled; m : small_number): pointer;
  label reswitch, common_ending, exit;
  var r: pointer; { the box node that will be returned }
      k: pointer; { points to a kanji_space specification }
      disp: scaled; { displacement }
      q: pointer; { trails behind p }

**690.** When a box is being appended to the current vertical list, the baselineskip calculation is handled by the *append\_to\_vlist* routine.

```

procedure append_to_vlist(b : pointer);
  var d: scaled; { deficiency of space between baselines }
      p: pointer; { a new glue node }
  begin if prev_depth > ignore_depth then
    begin d ← width(baseline_skip) – prev_depth – height(b);
    if d < line_skip_limit then p ← new_param_glue(line_skip_code)
    else begin p ← new_skip_param(baseline_skip_code); width(temp_ptr) ← d; { temp_ptr = glue_ptr(p) }
    end;
    link(tail) ← p; tail ← p;
    end;
  link(tail) ← b; tail ← b; prev_depth ← depth(b);
end;

```

**691. Data structures for math mode.** When T<sub>E</sub>X reads a formula that is enclosed between  $\$$ 's, it constructs an *mlist*, which is essentially a tree structure representing that formula. An *mlist* is a linear sequence of items, but we can regard it as a tree structure because *mlists* can appear within *mlists*. For example, many of the entries can be subscripted or superscripted, and such “scripts” are *mlists* in their own right.

An entire formula is parsed into such a tree before any of the actual typesetting is done, because the current style of type is usually not known until the formula has been fully scanned. For example, when the formula  $\$a+b \over c+d\$$  is being read, there is no way to tell that ‘ $a+b$ ’ will be in script size until ‘ $\over$ ’ has appeared.

During the scanning process, each element of the *mlist* being built is classified as a relation, a binary operator, an open parenthesis, etc., or as a construct like ‘ $\sqrt$ ’ that must be built up. This classification appears in the *mlist* data structure.

After a formula has been fully scanned, the *mlist* is converted to an *hlist* so that it can be incorporated into the surrounding text. This conversion is controlled by a recursive procedure that decides all of the appropriate styles by a “top-down” process starting at the outermost level and working in towards the subformulas. The formula is ultimately pasted together using combinations of horizontal and vertical boxes, with glue and penalty nodes inserted as necessary.

An *mlist* is represented internally as a linked list consisting chiefly of “noads” (pronounced “no-adds”), to distinguish them from the somewhat similar “nodes” in *hlists* and *vlists*. Certain kinds of ordinary nodes are allowed to appear in *mlists* together with the noads; T<sub>E</sub>X tells the difference by means of the *type* field, since a noad’s *type* is always greater than that of a node. An *mlist* does not contain character nodes, *hlist* nodes, *vlist* nodes, math nodes, ligature nodes, or unset nodes; in particular, each *mlist* item appears in the variable-size part of *mem*, so the *type* field is always present.

**692.** Each noad is four or more words long. The first word contains the *type* and *subtype* and *link* fields that are already so familiar to us; the second, third, and fourth words are called the noad's *nucleus*, *subscr*, and *supscr* fields.

Consider, for example, the simple formula '\$x^2\$', which would be parsed into an mlist containing a single element called an *ord\_noad*. The *nucleus* of this noad is a representation of 'x', the *subscr* is empty, and the *supscr* is a representation of '2'.

The *nucleus*, *subscr*, and *supscr* fields are further broken into subfields. If *p* points to a noad, and if *q* is one of its principal fields (e.g.,  $q = \text{subscr}(p)$ ), there are several possibilities for the subfields, depending on the *math\_type* of *q*.

*math\_type*(*q*) = *math\_char* means that *fam*(*q*) refers to one of the sixteen font families, and *character*(*q*) is the number of a character within a font of that family, as in a character node.

*math\_type*(*q*) = *math\_text\_char* is similar, but the character is unsubscripted and unsuperscripted and it is followed immediately by another character from the same font. (This *math\_type* setting appears only briefly during the processing; it is used to suppress unwanted italic corrections.)

*math\_type*(*q*) = *empty* indicates a field with no value (the corresponding attribute of noad *p* is not present).

*math\_type*(*q*) = *sub\_box* means that *info*(*q*) points to a box node (either an *hlist\_node* or a *vlist\_node*) that should be used as the value of the field. The *shift\_amount* in the subsidiary box node is the amount by which that box will be shifted downward.

*math\_type*(*q*) = *sub\_mlist* means that *info*(*q*) points to an mlist; the mlist must be converted to an hlist in order to obtain the value of this field.

In the latter case, we might have *info*(*q*) = *null*. This is not the same as *math\_type*(*q*) = *empty*; for example, '\$P\_{}\$' and '\$P\$' produce different results (the former will not have the "italic correction" added to the width of *P*, but the "script skip" will be added).

The definitions of subfields given here are evidently wasteful of space, since a halfword is being used for the *math\_type* although only three bits would be needed. However, there are hardly ever many noads present at once, since they are soon converted to nodes that take up even more space, so we can afford to represent them in whatever way simplifies the programming.

In Japanese, *math\_type*(*q*) = *math\_jchar* means that *fam*(*q*) refers to one of the sixteen kanji font families, and *KANJI*(*q*) is the internal kanji code number.

```

define noad_size = 5 { number of words in a normal noad }
define nucleus(#) ≡ # + 1 { the nucleus field of a noad }
define supscr(#) ≡ # + 2 { the supscr field of a noad }
define subscr(#) ≡ # + 3 { the subscr field of a noad }
define kcode_noad(#) ≡ # + 4
define math_kcode(#) ≡ info(# + 4) { the kanji character field of a noad }
define kcode_noad_nucleus(#) ≡ # + 3
define math_kcode_nucleus(#) ≡ info(# + 3) { the kanji character field offset from nucleus }
define math_jchar = 5
define math_text_jchar = 6
define math_type ≡ link { a halfword in mem }
define fam ≡ font { a quarterword in mem }
define math_char = 1 { math_type when the attribute is simple }
define sub_box = 2 { math_type when the attribute is a box }
define sub_mlist = 3 { math_type when the attribute is a formula }
define math_text_char = 4 { math_type when italic correction is dubious }

```

**693.** Each portion of a formula is classified as Ord, Op, Bin, Rel, Ope, Clo, Pun, or Inn, for purposes of spacing and line breaking. An *ord\_noad*, *op\_noad*, *bin\_noad*, *rel\_noad*, *open\_noad*, *close\_noad*, *punct\_noad*, or *inner\_noad* is used to represent portions of the various types. For example, an ‘=’ sign in a formula leads to the creation of a *rel\_noad* whose *nucleus* field is a representation of an equals sign (usually *fam* = 0, *character* = ‘75’). A formula preceded by `\mathrel` also results in a *rel\_noad*. When a *rel\_noad* is followed by an *op\_noad*, say, and possibly separated by one or more ordinary nodes (not noads), T<sub>E</sub>X will insert a penalty node (with the current *rel\_penalty*) just after the formula that corresponds to the *rel\_noad*, unless there already was a penalty immediately following; and a “thick space” will be inserted just before the formula that corresponds to the *op\_noad*.

A noad of type *ord\_noad*, *op\_noad*, . . . , *inner\_noad* usually has a *subtype* = *normal*. The only exception is that an *op\_noad* might have *subtype* = *limits* or *no\_limits*, if the normal positioning of limits has been overridden for this operator.

```

define ord_noad = unset_node + 3 { type of a noad classified Ord }
define op_noad = ord_noad + 1 { type of a noad classified Op }
define bin_noad = ord_noad + 2 { type of a noad classified Bin }
define rel_noad = ord_noad + 3 { type of a noad classified Rel }
define open_noad = ord_noad + 4 { type of a noad classified Ope }
define close_noad = ord_noad + 5 { type of a noad classified Clo }
define punct_noad = ord_noad + 6 { type of a noad classified Pun }
define inner_noad = ord_noad + 7 { type of a noad classified Inn }
define limits = 1 { subtype of op_noad whose scripts are to be above, below }
define no_limits = 2 { subtype of op_noad whose scripts are to be normal }

```

**694.** A *radical\_noad* is five words long; the fifth word is the *left\_delimiter* field, which usually represents a square root sign.

A *fraction\_noad* is six words long; it has a *right\_delimiter* field as well as a *left\_delimiter*.

Delimiter fields are of type *four\_quarters*, and they have four subfields called *small\_fam*, *small\_char*, *large\_fam*, *large\_char*. These subfields represent variable-size delimiters by giving the “small” and “large” starting characters, as explained in Chapter 17 of *The T<sub>E</sub>Xbook*.

A *fraction\_noad* is actually quite different from all other noads. Not only does it have six words, it has *thickness*, *denominator*, and *numerator* fields instead of *nucleus*, *subscr*, and *supscr*. The *thickness* is a scaled value that tells how thick to make a fraction rule; however, the special value *default\_code* is used to stand for the *default\_rule\_thickness* of the current size. The *numerator* and *denominator* point to mlists that define a fraction; we always have

$$\mathit{math\_type}(\mathit{numerator}) = \mathit{math\_type}(\mathit{denominator}) = \mathit{sub\_mlist}.$$

The *left\_delimiter* and *right\_delimiter* fields specify delimiters that will be placed at the left and right of the fraction. In this way, a *fraction\_noad* is able to represent all of T<sub>E</sub>X’s operators  $\backslash\over$ ,  $\backslash\atop$ ,  $\backslash\above$ ,  $\backslash\overwithdelims$ ,  $\backslash\atopwithdelims$ , and  $\backslash\abovewithdelims$ .

```

define left_delimiter(#) ≡ # + 5 { first delimiter field of a noad }
define right_delimiter(#) ≡ # + 4 { second delimiter field of a fraction noad }
define radical_noad = inner_noad + 1 { type of a noad for square roots }
define radical_noad_size = 6 { number of mem words in a radical noad }
define fraction_noad = radical_noad + 1 { type of a noad for generalized fractions }
define fraction_noad_size = 6 { number of mem words in a fraction noad }
define small_fam(#) ≡ mem[#].qqqq.b0 { fam for “small” delimiter }
define small_char(#) ≡ mem[#].qqqq.b1 { character for “small” delimiter }
define large_fam(#) ≡ mem[#].qqqq.b2 { fam for “large” delimiter }
define large_char(#) ≡ mem[#].qqqq.b3 { character for “large” delimiter }
define thickness ≡ width { thickness field in a fraction noad }
define default_code ≡ '10000000000 { denotes default_rule_thickness }
define numerator ≡ supscr { numerator field in a fraction noad }
define denominator ≡ subscr { denominator field in a fraction noad }

```

**695.** The global variable *empty\_field* is set up for initialization of empty fields in new noads. Similarly, *null\_delimiter* is for the initialization of delimiter fields.

```

⟨Global variables 13⟩ +=
empty_field: two_halves;
null_delimiter: four_quarters;

```

**696.** ⟨Set initial values of key variables 21⟩ +=

```

empty_field.rh ← empty; empty_field.lh ← null;
null_delimiter.b0 ← 0; null_delimiter.b1 ← min_quarterword;
null_delimiter.b2 ← 0; null_delimiter.b3 ← min_quarterword;

```

**697.** The *new\_noad* function creates an *ord\_noad* that is completely null.

```

function new_noad: pointer;
var p: pointer;
begin p ← get_node(noad_size); type(p) ← ord_noad; subtype(p) ← normal;
mem[nucleus(p)].hh ← empty_field; mem[subscr(p)].hh ← empty_field;
mem[supscr(p)].hh ← empty_field; mem[kcode_noad(p)].hh ← empty_field; new_noad ← p;
end;

```

**698.** A few more kinds of noads will complete the set: An *under\_noad* has its nucleus underlined; an *over\_noad* has it overlined. An *accent\_noad* places an accent over its nucleus; the accent character appears as *fam(accent\_chr(p))* and *character(accent\_chr(p))*. A *vcenter\_noad* centers its nucleus vertically with respect to the axis of the formula; in such noads we always have *math\_type(nucleus(p)) = sub\_box*.

And finally, we have *left\_noad* and *right\_noad* types, to implement T<sub>E</sub>X's `\left` and `\right`. The *nucleus* of such noads is replaced by a *delimiter* field; thus, for example, `\left C` produces a *left\_noad* such that *delimiter(p)* holds the family and character codes for all left parentheses. A *left\_noad* never appears in an mlist except as the first element, and a *right\_noad* never appears in an mlist except as the last element; furthermore, we either have both a *left\_noad* and a *right\_noad*, or neither one is present. The *subscr* and *supscr* fields are always *empty* in a *left\_noad* and a *right\_noad*.

```

define under_noad = fraction_noad + 1 { type of a noad for underlining }
define over_noad = under_noad + 1 { type of a noad for overlining }
define accent_noad = over_noad + 1 { type of a noad for accented subformulas }
define accent_noad_size = 6 { number of mem words in an accent noad }
define accent_chr(#) ≡ # + 5 { the accent_chr field of an accent noad }
define vcenter_noad = accent_noad + 1 { type of a noad for \vcenter }
define left_noad = vcenter_noad + 1 { type of a noad for \left }
define right_noad = left_noad + 1 { type of a noad for \right }
define delimiter ≡ nucleus { delimiter field in left and right noads }
define scripts_allowed(#) ≡ (type(#) ≥ ord_noad) ∧ (type(#) < left_noad)

```

**699.** Math formulas can also contain instructions like `\textstyle` that override T<sub>E</sub>X's normal style rules. A *style\_node* is inserted into the data structure to record such instructions; it is three words long, so it is considered a node instead of a noad. The *subtype* is either *display\_style* or *text\_style* or *script\_style* or *script\_script\_style*. The second and third words of a *style\_node* are not used, but they are present because a *choice\_node* is converted to a *style\_node*.

T<sub>E</sub>X uses even numbers 0, 2, 4, 6 to encode the basic styles *display\_style*, ..., *script\_script\_style*, and adds 1 to get the “cramped” versions of these styles. This gives a numerical order that is backwards from the convention of Appendix G in *The T<sub>E</sub>Xbook*; i.e., a smaller style has a larger numerical value.

```

define style_node = unset_node + 1 { type of a style node }
define style_node_size = 3 { number of words in a style node }
define display_style = 0 { subtype for \displaystyle }
define text_style = 2 { subtype for \textstyle }
define script_style = 4 { subtype for \scriptstyle }
define script_script_style = 6 { subtype for \scriptscriptstyle }
define cramped = 1 { add this to an uncramped style if you want to cramp it }
function new_style(s : small_number): pointer; { create a style node }
var p: pointer; { the new node }
begin p ← get_node(style_node_size); type(p) ← style_node; subtype(p) ← s; width(p) ← 0;
depth(p) ← 0; { the width and depth are not used }
new_style ← p;
end;

```

**700.** Finally, the `\mathchoice` primitive creates a *choice\_node*, which has special subfields *display\_mlist*, *text\_mlist*, *script\_mlist*, and *script\_script\_mlist* pointing to the mlists for each style.

```

define choice_node = unset_node + 2 { type of a choice node }
define display_mlist(#) ≡ info(# + 1) { mlist to be used in display style }
define text_mlist(#) ≡ link(# + 1) { mlist to be used in text style }
define script_mlist(#) ≡ info(# + 2) { mlist to be used in script style }
define script_script_mlist(#) ≡ link(# + 2) { mlist to be used in scriptscript style }
function new_choice: pointer; { create a choice node }
  var p: pointer; { the new node }
  begin p ← get_node(style_node_size); type(p) ← choice_node; subtype(p) ← 0;
    { the subtype is not used }
  display_mlist(p) ← null; text_mlist(p) ← null; script_mlist(p) ← null; script_script_mlist(p) ← null;
  new_choice ← p;
end;

```

**701.** Let's consider now the previously unwritten part of *show\_node\_list* that displays the things that can only be present in mlists; this program illustrates how to access the data structures just defined.

In the context of the following program, *p* points to a node or noad that should be displayed, and the current string contains the "recursion history" that leads to this point. The recursion history consists of a dot for each outer level in which *p* is subsidiary to some node, or in which *p* is subsidiary to the *nucleus* field of some noad; the dot is replaced by '`_`' or '`^`' or '`/`' or '`\`' if *p* is descended from the *subscr* or *supscr* or *denominator* or *numerator* fields of noads. For example, the current string would be '`.^._/`' if *p* points to the *ord\_noad* for *x* in the (ridiculous) formula '`\sqrt{a^{\mathinner{\b_{c\over x+y}}}}`'.

```

⟨Cases of show_node_list that arise in mlists only 701⟩ ≡
style_node: print_style(subtype(p));
choice_node: ⟨Display choice node p 706⟩;
ord_noad, op_noad, bin_noad, rel_noad, open_noad, close_noad, punct_noad,
  inner_noad, radical_noad, over_noad, under_noad, vcenter_noad, accent_noad, left_noad, right_noad:
  ⟨Display normal noad p 707⟩;
fraction_noad: ⟨Display fraction noad p 708⟩;
This code is used in section 189.

```

**702.** Here are some simple routines used in the display of noads.

```

⟨Declare procedures needed for displaying the elements of mlists 702⟩ ≡
procedure print_fam_and_char(p: pointer; t: small_number); { prints family and character }
  var cx: KANJI_code; { temporary register for KANJI }
  begin print_esc("fam"); print_int(fam(p)); print_char("␣");
  if t = math_char then print_ASCII(qo(character(p)))
  else begin KANJI(cx) ← math_kcode_nucleus(p); print_kanji(cx);
  end;
end;
procedure print_delimiter(p: pointer); { prints a delimiter as 24-bit hex value }
  var a: integer; { accumulator }
  begin a ← small_fam(p) * 256 + qo(small_char(p));
  a ← a * 1000 + large_fam(p) * 256 + qo(large_char(p));
  if a < 0 then print_int(a) { this should never happen }
  else print_hex(a);
  end;

```

See also sections 703 and 705.

This code is used in section 185.

**703.** The next subroutine will descend to another level of recursion when a subsidiary mlist needs to be displayed. The parameter  $c$  indicates what character is to become part of the recursion history. An empty mlist is distinguished from a field with  $math\_type(p) = empty$ , because these are not equivalent (as explained above).

```

⟨Declare procedures needed for displaying the elements of mlists 702⟩ +≡
procedure show_info; forward; { show_node_list(info(temp_ptr)) }
procedure print_subsidary_data(p : pointer; c : ASCII_code); { display a noad field }
  begin if cur_length ≥ depth_threshold then
    begin if math_type(p) ≠ empty then print("_[]");
    end
  else begin append_char(c); { include c in the recursion history }
    temp_ptr ← p; { prepare for show_info if recursion is needed }
    case math_type(p) of
      math_char, math_jchar: begin print_ln; print_current_string; print_fam_and_char(p, math_type(p));
      end;
      sub_box: show_info; { recursive call }
      sub_mlist: if info(p) = null then
        begin print_ln; print_current_string; print("{}");
        end
      else show_info; { recursive call }
    othercases do_nothing { empty }
  endcases;
  flush_char; { remove c from the recursion history }
end;
end;

```

**704.** The inelegant introduction of *show\_info* in the code above seems better than the alternative of using Pascal's strange *forward* declaration for a procedure with parameters. The Pascal convention about dropping parameters from a post-*forward* procedure is, frankly, so intolerable to the author of T<sub>E</sub>X that he would rather stoop to communication via a global temporary variable. (A similar stoopidity occurred with respect to *hlist\_out* and *vlist\_out* above, and it will occur with respect to *mlist\_to\_hlist* below.)

```

procedure show_info; { the reader will kindly forgive this }
  begin show_node_list(info(temp_ptr));
  end;

```

```

705. ⟨Declare procedures needed for displaying the elements of mlists 702⟩ +≡
procedure print_style(c : integer);
  begin case c div 2 of
    0: print_esc("displaystyle"); { display_style = 0 }
    1: print_esc("textstyle"); { text_style = 2 }
    2: print_esc("scriptstyle"); { script_style = 4 }
    3: print_esc("scriptscriptstyle"); { script_script_style = 6 }
  othercases print("Unknown_style!")
  endcases;
end;

```

**706.**  $\langle$  Display choice node  $p$  706  $\rangle \equiv$   
**begin** *print\_esc*("mathchoice"); *append\_char*("D"); *show\_node\_list*(*display\_mlist*( $p$ )); *flush\_char*;

  end;

```

This code is used in section 208.

**710. Subroutines for math mode.** In order to convert mlists to hlists, i.e., noads to nodes, we need several subroutines that are conveniently dealt with now.

Let us first introduce the macros that make it easy to get at the parameters and other font information. A size code, which is a multiple of 16, is added to a family number to get an index into the table of internal font numbers for each combination of family and size. (Be alert: Size codes get larger as the type gets smaller.)

```

define text_size = 0 {size code for the largest size in a family }
define script_size = 16 {size code for the medium size in a family }
define script_script_size = 32 {size code for the smallest size in a family }
⟨Basic printing procedures 58⟩ +=
procedure print_size(s : integer);
  begin if s = text_size then print_esc("textfont")
  else if s = script_size then print_esc("scriptfont")
    else print_esc("scriptscriptfont");
  end;

```

**711.** Before an mlist is converted to an hlist, T<sub>E</sub>X makes sure that the fonts in family 2 have enough parameters to be math-symbol fonts, and that the fonts in family 3 have enough parameters to be math-extension fonts. The math-symbol parameters are referred to by using the following macros, which take a size code as their parameter; for example, *num1*(*cur\_size*) gives the value of the *num1* parameter for the current size.

```

define mathsy_end(#) ≡ fam_fnt(2 + #) ] ] .sc
define mathsy(#) ≡ font_info [ # + param_base [ mathsy_end
define math_x_height ≡ mathsy(5) {height of 'x'}
define math_quad ≡ mathsy(6) {18mu}
define num1 ≡ mathsy(8) {numerator shift-up in display styles}
define num2 ≡ mathsy(9) {numerator shift-up in non-display, non-\atop}
define num3 ≡ mathsy(10) {numerator shift-up in non-display \atop}
define denom1 ≡ mathsy(11) {denominator shift-down in display styles}
define denom2 ≡ mathsy(12) {denominator shift-down in non-display styles}
define sup1 ≡ mathsy(13) {superscript shift-up in uncramped display style}
define sup2 ≡ mathsy(14) {superscript shift-up in uncramped non-display}
define sup3 ≡ mathsy(15) {superscript shift-up in cramped styles}
define sub1 ≡ mathsy(16) {subscript shift-down if superscript is absent}
define sub2 ≡ mathsy(17) {subscript shift-down if superscript is present}
define sup_drop ≡ mathsy(18) {superscript baseline below top of large box}
define sub_drop ≡ mathsy(19) {subscript baseline below bottom of large box}
define delim1 ≡ mathsy(20) {size of \atopwithdelims delimiters in display styles}
define delim2 ≡ mathsy(21) {size of \atopwithdelims delimiters in non-displays}
define axis_height ≡ mathsy(22) {height of fraction lines above the baseline}
define total.mathsy_params = 22

```

**712.** The math-extension parameters have similar macros, but the size code is omitted (since it is always *cur\_size* when we refer to such parameters).

```

define mathex(#) ≡ font_info[# + param_base[fam_fnt(3 + cur_size)]] .sc
define default_rule_thickness ≡ mathex(8) {thickness of \over bars}
define big_op_spacing1 ≡ mathex(9) {minimum clearance above a displayed op}
define big_op_spacing2 ≡ mathex(10) {minimum clearance below a displayed op}
define big_op_spacing3 ≡ mathex(11) {minimum baselineskip above displayed op}
define big_op_spacing4 ≡ mathex(12) {minimum baselineskip below displayed op}
define big_op_spacing5 ≡ mathex(13) {padding above and below displayed limits}
define total.mathex_params = 13

```

**713.** We also need to compute the change in style between mlists and their subsidiaries. The following macros define the subsidiary style for an overlined nucleus (*cramped\_style*), for a subscript or a superscript (*sub\_style* or *sup\_style*), or for a numerator or denominator (*num\_style* or *denom\_style*).

```

define cramped_style(#) ≡ 2 * (# div 2) + cramped {cramp the style}
define sub_style(#) ≡ 2 * (# div 4) + script_style + cramped {smaller and cramped}
define sup_style(#) ≡ 2 * (# div 4) + script_style + (# mod 2) {smaller}
define num_style(#) ≡ # + 2 - 2 * (# div 6) {smaller unless already script-script}
define denom_style(#) ≡ 2 * (# div 2) + cramped + 2 - 2 * (# div 6) {smaller, cramped}

```

**714.** When the style changes, the following piece of program computes associated information:

```

⟨Set up the values of cur_size and cur_mu, based on cur_style 714⟩ ≡
begin if cur_style < script_style then cur_size ← text_size
else cur_size ← 16 * ((cur_style - text_style) div 2);
cur_mu ← x.over_n(math_quad(cur_size), 18);
end

```

This code is used in sections 731, 737, 741, 765, 771, and 774.

**715.** Here is a function that returns a pointer to a rule node having a given thickness *t*. The rule will extend horizontally to the boundary of the vlist that eventually contains it.

```

function fraction_rule(t : scaled): pointer; {construct the bar for a fraction}
  var p: pointer; {the new node}
  begin p ← new_rule; height(p) ← t; depth(p) ← 0; fraction_rule ← p;
  end;

```

**716.** The *overbar* function returns a pointer to a vlist box that consists of a given box *b*, above which has been placed a kern of height *k* under a fraction rule of thickness *t* under additional space of height *t*.

```

function overbar(b : pointer; k, t : scaled): pointer;
  var p, q: pointer; {nodes being constructed}
  begin p ← new_kern(k); link(p) ← b; q ← fraction_rule(t); link(q) ← p; p ← new_kern(t); link(p) ← q;
  overbar ← vpack(p, natural);
  end;

```

**717.** The *var\_delimiter* function, which finds or constructs a sufficiently large delimiter, is the most interesting of the auxiliary functions that currently concern us. Given a pointer *d* to a delimiter field in some noad, together with a size code *s* and a vertical distance *v*, this function returns a pointer to a box that contains the smallest variant of *d* whose height plus depth is *v* or more. (And if no variant is large enough, it returns the largest available variant.) In particular, this routine will construct arbitrarily large delimiters from extensible components, if *d* leads to such characters.

The value returned is a box whose *shift\_amount* has been set so that the box is vertically centered with respect to the axis in the given size. If a built-up symbol is returned, the height of the box before shifting will be the height of its topmost component.

⟨Declare subprocedures for *var\_delimiter* 720⟩

```

function var_delimiter(d : pointer; s : small_number; v : scaled): pointer;
  label found, continue;
  var b: pointer; { the box that will be constructed }
      f, g: internal_font_number; { best-so-far and tentative font codes }
      c, x, y: quarterword; { best-so-far and tentative character codes }
      m, n: integer; { the number of extensible pieces }
      u: scaled; { height-plus-depth of a tentative character }
      w: scaled; { largest height-plus-depth so far }
      q: four_quarters; { character info }
      hd: eight_bits; { height-depth byte }
      r: four_quarters; { extensible pieces }
      z: small_number; { runs through font family members }
      large_attempt: boolean; { are we trying the "large" variant? }
  begin f ← null_font; w ← 0; large_attempt ← false; z ← small_fam(d); x ← small_char(d);
  loop begin ⟨Look at the variants of (z, x); set f and c whenever a better character is found; goto
    found as soon as a large enough variant is encountered 718⟩;
    if large_attempt then goto found; { there were none large enough }
    large_attempt ← true; z ← large_fam(d); x ← large_char(d);
  end;
  found: if f ≠ null_font then ⟨Make variable b point to a box for (f, c) 721⟩
  else begin b ← new_null_box; width(b) ← null_delimiter_space;
    { use this width if no delimiter was found }
  end;
  shift_amount(b) ← half(height(b) − depth(b)) − axis_height(s); var_delimiter ← b;
end;

```

**718.** The search process is complicated slightly by the facts that some of the characters might not be present in some of the fonts, and they might not be probed in increasing order of height.

⟨Look at the variants of (*z*, *x*); set *f* and *c* whenever a better character is found; **goto** *found* as soon as a large enough variant is encountered 718⟩ ≡

```

if (z ≠ 0) ∨ (x ≠ min_quarterword) then
  begin z ← z + s + 16;
  repeat z ← z − 16; g ← fam_fnt(z);
    if g ≠ null_font then ⟨Look at the list of characters starting with x in font g; set f and c whenever
      a better character is found; goto found as soon as a large enough variant is encountered 719⟩;
  until z < 16;
end

```

This code is used in section 717.

**719.**  $\langle$  Look at the list of characters starting with  $x$  in font  $g$ ; set  $f$  and  $c$  whenever a better character is found; **goto**  $found$  as soon as a large enough variant is encountered 719  $\rangle \equiv$

```

begin  $y \leftarrow x$ ;
if  $(qo(y) \geq font\_bc[g]) \wedge (qo(y) \leq font\_ec[g])$  then
  begin  $continue: q \leftarrow orig\_char\_info(g)(y)$ ;
  if  $char\_exists(q)$  then
    begin if  $char\_tag(q) = ext\_tag$  then
      begin  $f \leftarrow g$ ;  $c \leftarrow y$ ; goto  $found$ ;
    end;
     $hd \leftarrow height\_depth(q)$ ;  $u \leftarrow char\_height(g)(hd) + char\_depth(g)(hd)$ ;
    if  $u > w$  then
      begin  $f \leftarrow g$ ;  $c \leftarrow y$ ;  $w \leftarrow u$ ;
      if  $u \geq v$  then goto  $found$ ;
    end;
    if  $char\_tag(q) = list\_tag$  then
      begin  $y \leftarrow rem\_byte(q)$ ; goto  $continue$ ;
    end;
  end;
end;
end

```

This code is used in section 718.

**720.** Here is a subroutine that creates a new box, whose list contains a single character, and whose width includes the italic correction for that character. The height or depth of the box will be negative, if the height or depth of the character is negative; thus, this routine may deliver a slightly different result than *hpack* would produce.

$\langle$  Declare subprocedures for *var\_delimiter* 720  $\rangle \equiv$

```

function  $char\_box(f : internal\_font\_number; c : quarterword): pointer$ ;
  var  $q: four\_quarters; hd: eight\_bits; \{ height\_depth \text{ byte} \}$ 
   $b, p: pointer; \{ the \text{ new box and its character node} \}$ 
  begin  $q \leftarrow char\_info(f)(c)$ ;  $hd \leftarrow height\_depth(q)$ ;  $b \leftarrow new\_null\_box$ ;
   $width(b) \leftarrow char\_width(f)(q) + char\_italic(f)(q)$ ;  $height(b) \leftarrow char\_height(f)(hd)$ ;
   $depth(b) \leftarrow char\_depth(f)(hd)$ ;  $p \leftarrow get\_avail$ ;  $character(p) \leftarrow c$ ;  $font(p) \leftarrow f$ ;  $list\_ptr(b) \leftarrow p$ ;
   $char\_box \leftarrow b$ ;
  end;

```

See also sections 722 and 723.

This code is used in section 717.

**721.** When the following code is executed,  $char\_tag(q)$  will be equal to  $ext\_tag$  if and only if a built-up symbol is supposed to be returned.

$\langle$  Make variable  $b$  point to a box for  $(f, c)$  721  $\rangle \equiv$

```

if  $char\_tag(q) = ext\_tag$  then
   $\langle$  Construct an extensible character in a new box  $b$ , using recipe  $rem\_byte(q)$  and font  $f$  724  $\rangle$ 
else  $b \leftarrow char\_box(f, c)$ 

```

This code is used in section 717.

**722.** When we build an extensible character, it's handy to have the following subroutine, which puts a given character on top of the characters already in box  $b$ :

```

⟨ Declare subprocedures for var_delimiter 720 ⟩ +≡
procedure stack_into_box( $b$  : pointer;  $f$  : internal_font_number;  $c$  : quarterword);
  var  $p$  : pointer; { new node placed into  $b$  }
  begin  $p$  ← char_box( $f, c$ ); link( $p$ ) ← list_ptr( $b$ ); list_ptr( $b$ ) ←  $p$ ; height( $b$ ) ← height( $p$ );
  end;

```

**723.** Another handy subroutine computes the height plus depth of a given character:

```

⟨ Declare subprocedures for var_delimiter 720 ⟩ +≡
function height_plus_depth( $f$  : internal_font_number;  $c$  : quarterword): scaled;
  var  $q$  : four_quarters;  $hd$  : eight_bits; { height_depth byte }
  begin  $q$  ← char_info( $f$ )( $c$ );  $hd$  ← height_depth( $q$ );
  height_plus_depth ← char_height( $f$ )( $hd$ ) + char_depth( $f$ )( $hd$ );
  end;

```

**724.** ⟨ Construct an extensible character in a new box  $b$ , using recipe *rem\_byte*( $q$ ) and font  $f$  724 ⟩ ≡

```

begin  $b$  ← new_null_box; type( $b$ ) ← vlist_node;  $r$  ← font_info[exten_base[ $f$ ] + rem_byte( $q$ )].qqqq;
⟨ Compute the minimum suitable height,  $w$ , and the corresponding number of extension steps,  $n$ ; also set
  width( $b$ ) 725 ⟩;
 $c$  ← ext_bot( $r$ );
if  $c$  ≠ min_quarterword then stack_into_box( $b, f, c$ );
 $c$  ← ext_rep( $r$ );
for  $m$  ← 1 to  $n$  do stack_into_box( $b, f, c$ );
 $c$  ← ext_mid( $r$ );
if  $c$  ≠ min_quarterword then
  begin stack_into_box( $b, f, c$ );  $c$  ← ext_rep( $r$ );
  for  $m$  ← 1 to  $n$  do stack_into_box( $b, f, c$ );
  end;
 $c$  ← ext_top( $r$ );
if  $c$  ≠ min_quarterword then stack_into_box( $b, f, c$ );
depth( $b$ ) ←  $w$  - height( $b$ );
end

```

This code is used in section 721.

**725.** The width of an extensible character is the width of the repeatable module. If this module does not have positive height plus depth, we don't use any copies of it, otherwise we use as few as possible (in groups of two if there is a middle part).

⟨ Compute the minimum suitable height,  $w$ , and the corresponding number of extension steps,  $n$ ; also set

```

width(b) 725) ≡
c ← ext_rep(r); u ← height_plus_depth(f, c); w ← 0; q ← char_info(f)(c);
width(b) ← char_width(f)(q) + char_italic(f)(q);
c ← ext_bot(r); if c ≠ min_quarterword then w ← w + height_plus_depth(f, c);
c ← ext_mid(r); if c ≠ min_quarterword then w ← w + height_plus_depth(f, c);
c ← ext_top(r); if c ≠ min_quarterword then w ← w + height_plus_depth(f, c);
n ← 0;
if u > 0 then
  while w < v do
    begin w ← w + u; incr(n);
    if ext_mid(r) ≠ min_quarterword then w ← w + u;
    end

```

This code is used in section 724.

**726.** The next subroutine is much simpler; it is used for numerators and denominators of fractions as well as for displayed operators and their limits above and below. It takes a given box  $b$  and changes it so that the new box is centered in a box of width  $w$ . The centering is done by putting `\hss` glue at the left and right of the list inside  $b$ , then packaging the new box; thus, the actual box might not really be centered, if it already contains infinite glue.

The given box might contain a single character whose italic correction has been added to the width of the box; in this case a compensating kern is inserted.

```

function rebox(b : pointer; w : scaled): pointer;
var p: pointer; { temporary register for list manipulation }
    f: internal_font_number; { font in a one-character box }
    v: scaled; { width of a character without italic correction }
begin if (width(b) ≠ w) ∧ (list_ptr(b) ≠ null) then
  begin if type(b) ≠ hlist_node then b ← hpack(b, natural);
    p ← list_ptr(b);
    if is_char_node(p) then
      if font_dir[font(p)] ≠ dir_default then
        begin if link(link(p)) = null then
          begin f ← font(p); v ← char_width(f)(orig_char_info(f)(character(p)));
            if v ≠ width(b) then link(link(p)) ← new_kern(width(b) - v);
          end
        end
      else if link(p) = null then
        begin f ← font(p); v ← char_width(f)(orig_char_info(f)(character(p)));
          if v ≠ width(b) then link(p) ← new_kern(width(b) - v);
        end;
      delete_glue_ref(space_ptr(b)); delete_glue_ref(xspace_ptr(b)); free_node(b, box_node_size);
      b ← new_glue(ss_glue); link(b) ← p;
      while link(p) ≠ null do p ← link(p);
      link(p) ← new_glue(ss_glue); rebox ← hpack(b, w, exactly);
    end
  else begin width(b) ← w; rebox ← b;
    end;
end;
end;

```

**727.** Here is a subroutine that creates a new glue specification from another one that is expressed in ‘mu’, given the value of the math unit.

```

define mu_mult(#)  $\equiv$  nx_plus_y(n, #, xn_over_d(#, f, '200000))
function math_glue(g : pointer; m : scaled): pointer;
  var p: pointer; { the new glue specification }
      n: integer; { integer part of m }
      f: scaled; { fraction part of m }
  begin n  $\leftarrow$  x_over_n(m, '200000); f  $\leftarrow$  remainder;
  if f < 0 then
    begin decr(n); f  $\leftarrow$  f + '200000;
    end;
  p  $\leftarrow$  get_node(glue_spec_size); width(p)  $\leftarrow$  mu_mult(width(g)); { convert mu to pt }
  stretch_order(p)  $\leftarrow$  stretch_order(g);
  if stretch_order(p) = normal then stretch(p)  $\leftarrow$  mu_mult(stretch(g))
  else stretch(p)  $\leftarrow$  stretch(g);
  shrink_order(p)  $\leftarrow$  shrink_order(g);
  if shrink_order(p) = normal then shrink(p)  $\leftarrow$  mu_mult(shrink(g))
  else shrink(p)  $\leftarrow$  shrink(g);
  math_glue  $\leftarrow$  p;
  end;

```

**728.** The *math\_kern* subroutine removes *mu\_glue* from a kern node, given the value of the math unit.

```

procedure math_kern(p : pointer; m : scaled);
  var n: integer; { integer part of m }
      f: scaled; { fraction part of m }
  begin if subtype(p) = mu_glue then
    begin n  $\leftarrow$  x_over_n(m, '200000); f  $\leftarrow$  remainder;
    if f < 0 then
      begin decr(n); f  $\leftarrow$  f + '200000;
      end;
    width(p)  $\leftarrow$  mu_mult(width(p)); subtype(p)  $\leftarrow$  explicit;
    end;
  end;

```

**729.** Sometimes it is necessary to destroy an mlist. The following subroutine empties the current list, assuming that *abs(mode)* = *mmode*.

```

procedure flush_math;
  begin flush_node_list(link(head)); flush_node_list(incompleat_noad); link(head)  $\leftarrow$  null; tail  $\leftarrow$  head;
  incompleat_noad  $\leftarrow$  null;
  end;

```

**730. Typesetting math formulas.** T<sub>E</sub>X's most important routine for dealing with formulas is called *mlist\_to\_hlist*. After a formula has been scanned and represented as an mlist, this routine converts it to an hlist that can be placed into a box or incorporated into the text of a paragraph. There are three implicit parameters, passed in global variables: *cur\_mlist* points to the first node or noad in the given mlist (and it might be *null*); *cur\_style* is a style code; and *mlist\_penalties* is *true* if penalty nodes for potential line breaks are to be inserted into the resulting hlist. After *mlist\_to\_hlist* has acted, *link(temp\_head)* points to the translated hlist.

Since mlists can be inside mlists, the procedure is recursive. And since this is not part of T<sub>E</sub>X's inner loop, the program has been written in a manner that stresses compactness over efficiency.

```

⟨Global variables 13⟩ +≡
cur_mlist: pointer; {beginning of mlist to be translated}
cur_style: small_number; {style code at current place in the list}
cur_size: small_number; {size code corresponding to cur_style}
cur_mu: scaled; {the math unit width corresponding to cur_size}
mlist_penalties: boolean; {should mlist_to_hlist insert penalties?}

```

**731.** The recursion in *mlist\_to\_hlist* is due primarily to a subroutine called *clean\_box* that puts a given noad field into a box using a given math style; *mlist\_to\_hlist* can call *clean\_box*, which can call *mlist\_to\_hlist*.

The box returned by *clean\_box* is “clean” in the sense that its *shift\_amount* is zero.

**procedure** *mlist\_to\_hlist*; *forward*;

**function** *clean\_box*(*p* : *pointer*; *s* : *small\_number*; *jc* : *halfword*): *pointer*;

**label** *found*;

**var** *q*: *pointer*; {beginning of a list to be boxed}

*save\_style*: *small\_number*; {*cur\_style* to be restored}

*x*: *pointer*; {box to be returned}

*r*: *pointer*; {temporary pointer}

**begin case** *math\_type*(*p*) **of**

*math\_char*: **begin** *cur\_mlist* ← *new\_noad*; *mem*[*nucleus*(*cur\_mlist*)] ← *mem*[*p*];

**end**;

*math\_jchar*: **begin** *cur\_mlist* ← *new\_noad*; *mem*[*nucleus*(*cur\_mlist*)] ← *mem*[*p*];

*math\_kcode*(*cur\_mlist*) ← *jc*;

**end**;

*sub\_box*: **begin** *q* ← *info*(*p*); **goto** *found*;

**end**;

*sub\_mlist*: *cur\_mlist* ← *info*(*p*);

**othercases begin** *q* ← *new\_null\_box*; **goto** *found*;

**end**

**endcases**;

*save\_style* ← *cur\_style*; *cur\_style* ← *s*; *mlist\_penalties* ← *false*;

*mlist\_to\_hlist*; *q* ← *link*(*temp\_head*); {recursive call}

*cur\_style* ← *save\_style*; {restore the style}

⟨Set up the values of *cur\_size* and *cur\_mu*, based on *cur\_style* 714⟩;

*found*: **if** *is\_char\_node*(*q*) ∨ (*q* = *null*) **then** *x* ← *hpack*(*q*, *natural*)

**else if** (*link*(*q*) = *null*) ∧ (*type*(*q*) ≤ *dir\_node*) ∧ (*shift\_amount*(*q*) = 0) **then** *x* ← *q* {it's already clean}

**else** *x* ← *hpack*(*q*, *natural*);

⟨Simplify a trivial box 732⟩;

*clean\_box* ← *x*;

**end**;

**732.** Here we save memory space in a common case.

```

⟨Simplify a trivial box 732⟩ ≡
  q ← list_ptr(x);
  if is_char_node(q) then
    begin if font_dir[font(q)] ≠ dir_default then q ← link(q);
           r ← link(q);
           if r ≠ null then
             if link(r) = null then
               if ¬is_char_node(r) then
                 if type(r) = kern_node then { unneeded italic correction }
                   begin free_node(r, small_node_size); link(q) ← null;
                   end;
             end;
          end
end

```

This code is used in section 731.

**733.** It is convenient to have a procedure that converts a *math\_char* field to an “unpacked” form. The *fetch* routine sets *cur\_f*, *cur\_c*, and *cur\_i* to the font code, character code, and character information bytes of a given noad field. It also takes care of issuing error messages for nonexistent characters; in such cases, *char\_exists(cur\_i)* will be *false* after *fetch* has acted, and the field will also have been reset to *empty*.

```

procedure fetch(a: pointer); { unpack the math_char field a }
begin cur_c ← character(a); cur_f ← fam_fnt(fam(a) + cur_size);
if cur_f = null_font then ⟨Complain about an undefined family and set cur_i null 734⟩
else begin if font_dir[cur_f] ≠ dir_default then
  cur_c ← qi(get_jfm_pos(KANJI(math_kcode_nucleus(a)), cur_f));
  if (qo(cur_c) ≥ font_bc[cur_f]) ∧ (qo(cur_c) ≤ font_ec[cur_f]) then
    cur_i ← orig_char_info(cur_f)(cur_c)
  else cur_i ← null_character;
  if ¬(char_exists(cur_i)) then
    begin char_warning(cur_f, qo(cur_c)); math_type(a) ← empty;
    end;
  end;
end;
end;

```

```

734. ⟨Complain about an undefined family and set cur_i null 734⟩ ≡
begin print_err(""); print_size(cur_size); print_char(" "); print_int(fam(a));

help4("Somewhere in the math formula just ended, you used the")
("stated character from an undefined font family. For example,")
("plain TeX doesn't allow \it or \sl in subscripts. Proceed,")
("and I'll try to forget that I needed that character."); error; cur_i ← null_character;
math_type(a) ← empty;
end

```

This code is used in section 733.

**735.** The outputs of *fetch* are placed in global variables.

```

⟨Global variables 13⟩ +≡
cur_f: internal_font_number; { the font field of a math_char }
cur_c: quarterword; { the character field of a math_char }
cur_i: four_quarters; { the char_info of a math_char, or a lig/kern instruction }

```

**736.** We need to do a lot of different things, so *mlist\_to\_hlist* makes two passes over the given mlist.

The first pass does most of the processing: It removes “mu” spacing from glue, it recursively evaluates all subsidiary mlists so that only the top-level mlist remains to be handled, it puts fractions and square roots and such things into boxes, it attaches subscripts and superscripts, and it computes the overall height and depth of the top-level mlist so that the size of delimiters for a *left\_noad* and a *right\_noad* will be known. The hlist resulting from each noad is recorded in that noad’s *new\_hlist* field, an integer field that replaces the *nucleus* or *thickness*.

The second pass eliminates all noads and inserts the correct glue and penalties between nodes.

```
define new_hlist(#)  $\equiv$  mem[nucleus(#)].int { the translation of an mlist }
```

**737.** Here is the overall plan of *mlist\_to\_hlist*, and the list of its local variables.

```
define done_with_noad = 80 { go here when a noad has been fully translated }
```

```
define done_with_node = 81 { go here when a node has been fully converted }
```

```
define check_dimensions = 82 { go here to update max_h and max_d }
```

```
define delete_q = 83 { go here to delete q and move to the next node }
```

⟨Declare math construction procedures 745⟩

```
procedure mlist_to_hlist;
```

```
label reswitch, check_dimensions, done_with_noad, done_with_node, delete_q, done;
```

```
var mlist: pointer; { beginning of the given list }
```

```
  penalties: boolean; { should penalty nodes be inserted? }
```

```
  style: small_number; { the given style }
```

```
  u: pointer; { temporary register }
```

```
  save_style: small_number; { holds cur_style during recursion }
```

```
  q: pointer; { runs through the mlist }
```

```
  r: pointer; { the most recent noad preceding q }
```

```
  r_type: small_number; { the type of noad r, or op_noad if r = null }
```

```
  t: small_number; { the effective type of noad q during the second pass }
```

```
  p, x, y, z: pointer; { temporary registers for list construction }
```

```
  pen: integer; { a penalty to be inserted }
```

```
  s: small_number; { the size of a noad to be deleted }
```

```
  max_h, max_d: scaled; { maximum height and depth of the list translated so far }
```

```
  delta: scaled; { offset between subscript and superscript }
```

```
begin mlist  $\leftarrow$  cur_mlist; penalties  $\leftarrow$  mlist_penalties; style  $\leftarrow$  cur_style;
```

```
  { tuck global parameters away as local variables }
```

```
q  $\leftarrow$  mlist; r  $\leftarrow$  null; r_type  $\leftarrow$  op_noad; max_h  $\leftarrow$  0; max_d  $\leftarrow$  0;
```

```
⟨Set up the values of cur_size and cur_mu, based on cur_style 714⟩;
```

```
while q  $\neq$  null do ⟨Process node-or-noad q as much as possible in preparation for the second pass of mlist_to_hlist, then move to the next item in the mlist 738⟩;
```

```
⟨Convert a final bin_noad to an ord_noad 740⟩;
```

```
⟨Make a second pass over the mlist, removing all noads and inserting the proper spacing and penalties 771⟩;
```

```
p  $\leftarrow$  new_null_box; link(p)  $\leftarrow$  link(temp_head); adjust_hlist(p, false); link(temp_head)  $\leftarrow$  link(p);
```

```
delete_glue_ref(space_ptr(p)); delete_glue_ref(xspace_ptr(p)); free_node(p, box_node_size);
```

```
end;
```

**738.** We use the fact that no character nodes appear in an mlist, hence the field  $type(q)$  is always present.  
 ⟨Process node-or-noad  $q$  as much as possible in preparation for the second pass of  $mlist\_to\_hlist$ , then move to the next item in the mlist 738⟩ ≡

```

begin ⟨Do first-pass processing based on  $type(q)$ ; goto  $done\_with\_noad$  if a noad has been fully
  processed, goto  $check\_dimensions$  if it has been translated into  $new\_hlist(q)$ , or goto  $done\_with\_node$ 
  if a node has been fully processed 739) ≡
 $check\_dimensions$ :  $z \leftarrow hpack(new\_hlist(q), natural)$ ;
if  $height(z) > max\_h$  then  $max\_h \leftarrow height(z)$ ;
if  $depth(z) > max\_d$  then  $max\_d \leftarrow depth(z)$ ;
   $delete\_glue\_ref(space\_ptr(z))$ ;  $delete\_glue\_ref(xspace\_ptr(z))$ ;  $free\_node(z, box\_node\_size)$ ;
 $done\_with\_noad$ :  $r \leftarrow q$ ;  $r\_type \leftarrow type(r)$ ;
 $done\_with\_node$ :  $q \leftarrow link(q)$ ;
end

```

This code is used in section 737.

**739.** One of the things we must do on the first pass is change a  $bin\_noad$  to an  $ord\_noad$  if the  $bin\_noad$  is not in the context of a binary operator. The values of  $r$  and  $r\_type$  make this fairly easy.

⟨Do first-pass processing based on  $type(q)$ ; **goto**  $done\_with\_noad$  if a noad has been fully processed, **goto**  $check\_dimensions$  if it has been translated into  $new\_hlist(q)$ , or **goto**  $done\_with\_node$  if a node has been fully processed 739) ≡

```

vcenter_noad: make_vcenter(q);

```

This code is used in section 739.

**745.** Most of the actual construction work of *mlist\_to\_hlist* is done by procedures with names like *make\_fraction*, *make\_radical*, etc. To illustrate the general setup of such procedures, let's begin with a couple of simple ones.

```

⟨ Declare math construction procedures 745 ⟩ ≡
procedure make_over(q : pointer);
  begin info(nucleus(q)) ← overbar(clean_box(nucleus(q), cramped_style(cur_style), math_kcode(q)),
    3 * default_rule_thickness, default_rule_thickness); math_type(nucleus(q)) ← sub_box;
  end;

```

See also sections 746, 747, 748, 749, 754, 760, 763, 767, and 773.

This code is used in section 737.

**746.**  $\langle$  Declare math construction procedures 745  $\rangle + \equiv$

```
procedure make_under(q : pointer);
  var p, x, y: pointer; { temporary registers for box construction }
  delta: scaled; { overall height plus depth }
  begin x  $\leftarrow$  clean_box(nucleus(q), cur_style, math_kcode(q)); p  $\leftarrow$  new_kern(3 * default_rule_thickness);
  link(x)  $\leftarrow$  p; link(p)  $\leftarrow$  fraction_rule(default_rule_thickness); y  $\leftarrow$  vpack(x, natural);
  delta  $\leftarrow$  height(y) + depth(y) + default_rule_thickness; height(y)  $\leftarrow$  height(x);
  depth(y)  $\leftarrow$  delta - height(y); info(nucleus(q))  $\leftarrow$  y; math_type(nucleus(q))  $\leftarrow$  sub_box;
  end;
```

**747.**  $\langle$  Declare math construction procedures 745  $\rangle + \equiv$

```
procedure make_vcenter(q : pointer);
  var v: pointer; { the box that should be centered vertically }
  delta: scaled; { its height plus depth }
  begin v  $\leftarrow$  info(nucleus(q));
  if type(v) = dir_node then
    begin if type(list_ptr(v))  $\neq$  vlist_node then confusion("dircenter")
    end
  else begin if type(v)  $\neq$  vlist_node then confusion("vcenter")
  end;
  delta  $\leftarrow$  height(v) + depth(v); height(v)  $\leftarrow$  axis_height(cur_size) + half(delta);
  depth(v)  $\leftarrow$  delta - height(v);
  end;
```

**748.** According to the rules in the DVI file specifications, we ensure alignment between a square root sign and the rule above its nucleus by assuming that the baseline of the square-root symbol is the same as the bottom of the rule. The height of the square-root symbol will be the thickness of the rule, and the depth of the square-root symbol should exceed or equal the height-plus-depth of the nucleus plus a certain minimum clearance *clr*. The symbol will be placed so that the actual clearance is *clr* plus half the excess.

$\langle$  Declare math construction procedures 745  $\rangle + \equiv$

```
procedure make_radical(q : pointer);
  var x, y: pointer; { temporary registers for box construction }
  delta, clr: scaled; { dimensions involved in the calculation }
  begin x  $\leftarrow$  clean_box(nucleus(q), cramped_style(cur_style), math_kcode(q));
  if cur_style < text_style then { display style }
    clr  $\leftarrow$  default_rule_thickness + (abs(math_x_height(cur_size)) div 4)
  else begin clr  $\leftarrow$  default_rule_thickness; clr  $\leftarrow$  clr + (abs(clr) div 4);
  end;
  y  $\leftarrow$  var_delimiter(left_delimiter(q), cur_size, height(x) + depth(x) + clr + default_rule_thickness);
  delta  $\leftarrow$  depth(y) - (height(x) + depth(x) + clr);
  if delta > 0 then clr  $\leftarrow$  clr + half(delta); { increase the actual clearance }
  shift_amount(y)  $\leftarrow$  -(height(x) + clr); link(y)  $\leftarrow$  overbar(x, clr, height(y));
  info(nucleus(q))  $\leftarrow$  hpack(y, natural); math_type(nucleus(q))  $\leftarrow$  sub_box;
  end;
```

**749.** Slants are not considered when placing accents in math mode. The accenter is centered over the accentee, and the accent width is treated as zero with respect to the size of the final box.

⟨Declare math construction procedures 745⟩ +≡

```

procedure make_math_accent(q : pointer);
  label done, done1;

 $new\_hlist(q) \leftarrow hpack(x, natural)$

This code is used in section 754.

**760.** If the nucleus of an  $op\_noad$  is a single character, it is to be centered vertically with respect to the axis, after first being enlarged (via a character list in the font) if we are in display style. The normal convention for placing displayed limits is to put them above and below the operator in display style.

The italic correction is removed from the character if there is a subscript and the limits are not being displayed. The  $make\_op$  routine returns the value that should be used as an offset between subscript and superscript.

After  $make\_op$  has acted,  $subtype(q)$  will be  $limits$  if and only if the limits have been set above and below the operator. In that case,  $new\_hlist(q)$  will already contain the desired final box.

$\langle$  Declare math construction procedures 745  $\rangle + \equiv$

    end

```

This code is used in section 763.

**765.** When we get to the following part of the program, we have “fallen through” from cases that did not lead to *check\_dimensions* or *done\_with\_noad* or *done\_with\_node*. Thus, *q* points to a noad whose nucleus may need to be converted to an hlist, and whose subscripts and superscripts need to be appended if they are present.

If *nucleus(q)* is not a *math\_char*, the variable *delta* is the amount by which a superscript should be moved right with respect to a subscript when both are present.

```

⟨ Convert nucleus(q) to an hlist and attach the sub/superscripts 765 ⟩ ≡
  case math_type(nucleus(q)) of
    math_char, math_text_char, math_jchar, math_text_jchar: ⟨ Create a character node p for nucleus(q),
      possibly followed by a kern node for the italic correction, and set delta to the italic correction if a
      subscript is present 766 ⟩;
    empty: p ← null;
    sub_box: p ← info(nucleus(q));
    sub_mlist: begin cur_mlist ← info(nucleus(q)); save_style ← cur_style; mlist_penalties ← false;
      mlist_to_hlist; { recursive call }
      cur_style ← save_style; ⟨ Set up the values of cur_size and cur_mu, based on cur_style 714 ⟩;
      p ← hpack(link(temp_head), natural);
    end;
  othercases confusion("mlist2")
endcases;
  new_hlist(q) ← p;
  if (math_type(subscr(q)) = empty) ∧ (math_type(supscr(q)) = empty) then goto check_dimensions;
  make_scripts(q, delta)

```

This code is used in section 739.

**766.** ⟨ Create a character node *p* for *nucleus(q)*, possibly followed by a kern node for the italic correction, and set *delta* to the italic correction if a subscript is present 766 ⟩ ≡

```

begin fetch(nucleus(q));
if char_exists(cur_i) then
  begin delta ← char_italic(cur_f)(cur_i); p ← new_character(cur_f, qo(cur_c)); u ← p;
  if font_dir[cur_f] ≠ dir_default then
    begin link(u) ← get_avail; u ← link(u); info(u) ← math_kcode(q);
    end;
  if ((math_type(nucleus(q)) = math_text_char) ∨ (math_type(nucleus(q)) =
    math_text_jchar) ∧ (space(cur_f) ≠ 0) then delta ← 0; { no italic correction in
    mid-word of text font }
  if (math_type(subscr(q)) = empty) ∧ (delta ≠ 0) then
    begin link(u) ← new_kern(delta); delta ← 0;
    end;
  end
else p ← null;
end

```

This code is used in section 765.

**767.** The purpose of *make\_scripts*(*q*, *delta*) is to attach the subscript and/or superscript of noad *q* to the list that starts at *new\_hlist*(*q*), given that subscript and superscript aren't both empty. The superscript will appear to the right of the subscript by a given distance *delta*.

We set *shift\_down* and *shift\_up* to the minimum amounts to shift the baseline of subscripts and superscripts based on the given nucleus.

⟨Declare math construction procedures 745⟩ +≡

```

procedure make_scripts(q : pointer; delta : scaled);
  var p, x, y, z : pointer; { temporary registers for box construction }
      shift_up, shift_down, clr : scaled; { dimensions in the calculation }
      t : small_number; { subsidiary size code }
  begin p ← new_hlist(q);
  if is_char_node(p) then
    begin shift_up ← 0; shift_down ← 0;
    end
  else begin z ← hpack(p, natural);
    if cur_style < script_style then t ← script_size else t ← script_script_size;
    shift_up ← height(z) - sup_drop(t); shift_down ← depth(z) + sub_drop(t);
    delete_glue_ref(space_ptr(z)); delete_glue_ref(xspace_ptr(z)); free_node(z, box_node_size);
    end;
  if math_type(supscr(q)) = empty then ⟨Construct a subscript box x when there is no superscript 768⟩
  else begin ⟨Construct a superscript box x 769⟩;
    if math_type(subscr(q)) = empty then shift_amount(x) ← -shift_up
    else ⟨Construct a sub/superscript combination box x, with the superscript offset by delta 770⟩;
    end;
  if new_hlist(q) = null then new_hlist(q) ← x
  else begin p ← new_hlist(q);
    while link(p) ≠ null do p ← link(p);
    link(p) ← x;
    end;
  end;

```

**768.** When there is a subscript without a superscript, the top of the subscript should not exceed the baseline plus four-fifths of the x-height.

⟨Construct a subscript box *x* when there is no superscript 768⟩ ≡

```

begin x ← clean_box(subscr(q), sub_style(cur_style), math_kcode(q)); width(x) ← width(x) + script_space;
if shift_down < sub1(cur_size) then shift_down ← sub1(cur_size);
clr ← height(x) - (abs(math_x_height(cur_size) * 4) div 5);
if shift_down < clr then shift_down ← clr;
shift_amount(x) ← shift_down;
end

```

This code is used in section 767.

**769.** The bottom of a superscript should never descend below the baseline plus one-fourth of the x-height.

```

⟨Construct a superscript box  $x$  769⟩ ≡
  begin  $x \leftarrow \text{clean\_box}(\text{supscr}(q), \text{sup\_style}(\text{cur\_style}), \text{math\_kcode}(q)); \text{width}(x) \leftarrow \text{width}(x) + \text{script\_space};$ 
  if  $\text{odd}(\text{cur\_style})$  then  $\text{clr} \leftarrow \text{sup3}(\text{cur\_size})$ 
  else if  $\text{cur\_style} < \text{text\_style}$  then  $\text{clr} \leftarrow \text{sup1}(\text{cur\_size})$ 
    else  $\text{clr} \leftarrow \text{sup2}(\text{cur\_size});$ 
  if  $\text{shift\_up} < \text{clr}$  then  $\text{shift\_up} \leftarrow \text{clr};$ 
   $\text{clr} \leftarrow \text{depth}(x) + (\text{abs}(\text{math\_x\_height}(\text{cur\_size})) \text{div } 4);$ 
  if  $\text{shift\_up} < \text{clr}$  then  $\text{shift\_up} \leftarrow \text{clr};$ 
  end

```

This code is used in section 767.

**770.** When both subscript and superscript are present, the subscript must be separated from the superscript by at least four times *default\_rule\_thickness*. If this condition would be violated, the subscript moves down, after which both subscript and superscript move up so that the bottom of the superscript is at least as high as the baseline plus four-fifths of the x-height.

```

⟨Construct a sub/superscript combination box  $x$ , with the superscript offset by  $\delta$  770⟩ ≡
  begin  $y \leftarrow \text{clean\_box}(\text{subscr}(q), \text{sub\_style}(\text{cur\_style}), \text{math\_kcode}(q)); \text{width}(y) \leftarrow \text{width}(y) + \text{script\_space};$ 
  if  $\text{shift\_down} < \text{sub2}(\text{cur\_size})$  then  $\text{shift\_down} \leftarrow \text{sub2}(\text{cur\_size});$ 
   $\text{clr} \leftarrow 4 * \text{default\_rule\_thickness} - ((\text{shift\_up} - \text{depth}(x)) - (\text{height}(y) - \text{shift\_down}));$ 
  if  $\text{clr} > 0$  then
    begin  $\text{shift\_down} \leftarrow \text{shift\_down} + \text{clr};$ 
     $\text{clr} \leftarrow (\text{abs}(\text{math\_x\_height}(\text{cur\_size}) * 4) \text{div } 5) - (\text{shift\_up} - \text{depth}(x));$ 
    if  $\text{clr} > 0$  then
      begin  $\text{shift\_up} \leftarrow \text{shift\_up} + \text{clr}; \text{shift\_down} \leftarrow \text{shift\_down} - \text{clr};$ 
      end;
    end;
   $\text{shift\_amount}(x) \leftarrow \delta; \{ \text{superscript is } \delta \text{ to the right of the subscript } \}$ 
   $p \leftarrow \text{new\_kern}((\text{shift\_up} - \text{depth}(x)) - (\text{height}(y) - \text{shift\_down})); \text{link}(x) \leftarrow p; \text{link}(p) \leftarrow y;$ 
   $x \leftarrow \text{vpack}(x, \text{natural}); \text{shift\_amount}(x) \leftarrow \text{shift\_down};$ 
  end

```

This code is used in section 767.

**771.** We have now tied up all the loose ends of the first pass of *mlist\_to\_hlist*. The second pass simply goes through and hooks everything together with the proper glue and penalties. It also handles the *left\_noad* and *right\_noad* that might be present, since *max\_h* and *max\_d* are now known. Variable *p* points to a node at the current end of the final hlist.

```

⟨Make a second pass over the mlist, removing all noads and inserting the proper spacing and penalties 771⟩ ≡
   $p \leftarrow \text{temp\_head}; \text{link}(p) \leftarrow \text{null}; q \leftarrow \text{mlist}; r\_type \leftarrow 0; \text{cur\_style} \leftarrow \text{style};$ 
  ⟨Set up the values of  $\text{cur\_size}$  and  $\text{cur\_mu}$ , based on  $\text{cur\_style}$  714⟩;
  while  $q \neq \text{null}$  do
    begin ⟨If node  $q$  is a style node, change the style and goto delete_q; otherwise if it is not a noad, put it into the hlist, advance  $q$ , and goto done; otherwise set  $s$  to the size of noad  $q$ , set  $t$  to the associated type (ord_noad .. inner_noad), and set  $\text{pen}$  to the associated penalty 772⟩;
    ⟨Append inter-element spacing based on  $r\_type$  and  $t$  777⟩;
    ⟨Append any new_hlist entries for  $q$ , and any appropriate penalties 778⟩;
     $r\_type \leftarrow t;$ 
     $\text{delete\_q}: r \leftarrow q; q \leftarrow \text{link}(q); \text{free\_node}(r, s);$ 
     $\text{done}: \text{end}$ 

```

This code is used in section 737.

**772.** Just before doing the big **case** switch in the second pass, the program sets up default values so that most of the branches are short.

```

⟨If node q is a style node, change the style and goto delete_q; otherwise if it is not a noad, put it into the
  hlist, advance q, and goto done; otherwise set s to the size of noad q, set t to the associated type
  (ord_noad .. inner_noad), and set pen to the associated penalty 772) ≡
t ← ord_noad; s ← noad_size; pen ← inf_penalty;
case type(q) of
  op_noad, open_noad, close_noad, punct_noad, inner_noad: t ← type(q);
  bin_noad: begin t ← bin_noad; pen ← bin_op_penalty;
    end;
  rel_noad: begin t ← rel_noad; pen ← rel_penalty;
    end;
  ord_noad, vcenter_noad, over_noad, under_noad: do_nothing;
  radical_noad: s ← radical_noad_size;
  accent_noad: s ← accent_noad_size;
  fraction_noad: begin t ← inner_noad; s ← fraction_noad_size;
    end;
  left_noad, right_noad: t ← make_left_right(q, style, max_d, max_h);
  style_node: ⟨Change the current style and goto delete_q 774);
  whatsit_node, penalty_node, rule_node, disc_node, adjust_node, ins_node, mark_node, glue_node, kern_node:
    begin link(p) ← q; p ← q; q ← link(q); link(p) ← null; goto done;
    end;
  disp_node: begin link(p) ← q; p ← q; q ← link(q); link(p) ← null; goto done;
    end;
othercases confusion("mlist3")
endcases

```

This code is used in section 771.

**773.** The *make\_left\_right* function constructs a left or right delimiter of the required size and returns the value *open\_noad* or *close\_noad*. The *right\_noad* and *left\_noad* will both be based on the original *style*, so they will have consistent sizes.

We use the fact that  $right\_noad - left\_noad = close\_noad - open\_noad$ .

```

⟨Declare math construction procedures 745) +≡
function make_left_right(q : pointer; style : small_number; max_d, max_h : scaled): small_number;
  var delta, delta1, delta2: scaled; { dimensions used in the calculation }
  begin if style < script_style then cur_size ← text_size
  else cur_size ← 16 * ((style - text_style) div 2);
  delta2 ← max_d + axis_height(cur_size); delta1 ← max_h + max_d - delta2;
  if delta2 > delta1 then delta1 ← delta2; { delta1 is max distance from axis }
  delta ← (delta1 div 500) * delimiter_factor; delta2 ← delta1 + delta1 - delimiter_shortfall;
  if delta < delta2 then delta ← delta2;
  new_hlist(q) ← var_delimiter(delimiter(q), cur_size, delta);
  make_left_right ← type(q) - (left_noad - open_noad); { open_noad or close_noad }
  end;

```

```

774. ⟨Change the current style and goto delete_q 774) ≡
  begin cur_style ← subtype(q); s ← style_node_size;
  ⟨Set up the values of cur_size and cur_mu, based on cur_style 714);
  goto delete_q;
  end

```

This code is used in section 772.

**775.** The inter-element spacing in math formulas depends on a  $8 \times 8$  table that T<sub>E</sub>X preloads as a 64-digit string. The elements of this string have the following significance:

- 0 means no space;
- 1 means a conditional thin space (`\nonscript\mskip\thinmuskip`);
- 2 means a thin space (`\mskip\thinmuskip`);
- 3 means a conditional medium space (`\nonscript\mskip\medmuskip`);
- 4 means a conditional thick space (`\nonscript\mskip\thickmuskip`);
- \* means an impossible case.

This is all pretty cryptic, but *The T<sub>E</sub>Xbook* explains what is supposed to happen, and the string makes it happen.

A global variable `magic_offset` is computed so that if  $a$  and  $b$  are in the range `ord_noad .. inner_noad`, then `str_pool[a * 8 + b + magic_offset]` is the digit for spacing between noad types  $a$  and  $b$ .

If Pascal had provided a good way to preload constant arrays, this part of the program would not have been so strange.

```
define math_spacing =
"0234000122*4000133**3**344*0400400*000000234000111*1111112341011"
⟨Global variables 13⟩ +=
magic_offset: integer; { used to find inter-element spacing }
```

```
776. ⟨Compute the magic offset 776⟩ ≡
magic_offset ← str_start[math_spacing] - 9 * ord_noad
```

This code is used in section 1350.

```
777. ⟨Append inter-element spacing based on r_type and t 777⟩ ≡
if r_type > 0 then { not the first noad }
begin case so(str_pool[r_type * 8 + t + magic_offset]) of
"0": x ← 0;
"1": if cur_style < script_style then x ← thin_mu_skip_code else x ← 0;
"2": x ← thin_mu_skip_code;
"3": if cur_style < script_style then x ← med_mu_skip_code else x ← 0;
"4": if cur_style < script_style then x ← thick_mu_skip_code else x ← 0;
othercases confusion("mlist4")
endcases;
if x ≠ 0 then
begin y ← math_glue(glue_par(x), cur_mu); z ← new_glue(y); glue_ref_count(y) ← null;
link(p) ← z; p ← z;
subtype(z) ← x + 1; { store a symbolic subtype }
end;
end
```

This code is used in section 771.

**778.** We insert a penalty node after the hlist entries of noad  $q$  if  $pen$  is not an “infinite” penalty, and if the node immediately following  $q$  is not a penalty node or a *rel\_noad* or absent entirely.

(Append any *new\_hlist* entries for  $q$ , and any appropriate penalties 778)  $\equiv$

```

if new_hlist( $q$ )  $\neq$  null then
  begin link( $p$ )  $\leftarrow$  new_hlist( $q$ );
  repeat  $p \leftarrow link(p)$ ;
  until link( $p$ ) = null;
  end;
if penalties then
  if link( $q$ )  $\neq$  null then
    if  $pen < inf\_penalty$  then
      begin r_type  $\leftarrow$  type(link( $q$ ));
      if r_type  $\neq$  penalty_node then
        if r_type  $\neq$  rel_noad then
          begin  $z \leftarrow new\_penalty(pen)$ ; link( $p$ )  $\leftarrow$   $z$ ;  $p \leftarrow z$ ;
          end;
        end
      end
    end
  end

```

This code is used in section 771.

**779. Alignment.** It's sort of a miracle whenever `\halign` and `\valign` work, because they cut across so many of the control structures of T<sub>E</sub>X.

Therefore the present page is probably not the best place for a beginner to start reading this program; it is better to master everything else first.

Let us focus our thoughts on an example of what the input might be, in order to get some idea about how the alignment miracle happens. The example doesn't do anything useful, but it is sufficiently general to indicate all of the special cases that must be dealt with; please do not be disturbed by its apparent complexity and meaninglessness.

```

\tabskip 2pt plus 3pt
\halign to 300pt{u1#v1&
    \tabskip 1pt plus 1fil u2#v2&
    u3#v3\cr
a1&\omit a2&\vrule\cr
\noalign{\vskip 3pt}
b1\span b2\cr
\omit&c2\span\omit\cr}

```

Here's what happens:

(0) When `\halign to 300pt{}` is scanned, the *scan\_spec* routine places the 300pt dimension onto the *save\_stack*, and an *align\_group* code is placed above it. This will make it possible to complete the alignment when the matching `}` is found.

(1) The preamble is scanned next. Macros in the preamble are not expanded, except as part of a *tabskip* specification. For example, if `u2` had been a macro in the preamble above, it would have been expanded, since T<sub>E</sub>X must look for `'minus...'` as part of the *tabskip* glue. A “preamble list” is constructed based on the user's preamble; in our case it contains the following seven items:

<code>\glue 2pt plus 3pt</code>	(the <i>tabskip</i> preceding column 1)
<code>\alignrecord, width -∞</code>	(preamble info for column 1)
<code>\glue 2pt plus 3pt</code>	(the <i>tabskip</i> between columns 1 and 2)
<code>\alignrecord, width -∞</code>	(preamble info for column 2)
<code>\glue 1pt plus 1fil</code>	(the <i>tabskip</i> between columns 2 and 3)
<code>\alignrecord, width -∞</code>	(preamble info for column 3)
<code>\glue 1pt plus 1fil</code>	(the <i>tabskip</i> following column 3)

These “alignrecord” entries have the same size as an *unset\_node*, since they will later be converted into such nodes. However, at the moment they have no *type* or *subtype* fields; they have *info* fields instead, and these *info* fields are initially set to the value *end\_span*, for reasons explained below. Furthermore, the alignrecord nodes have no *height* or *depth* fields; these are renamed *u\_part* and *v\_part*, and they point to token lists for the templates of the alignment. For example, the *u\_part* field in the first alignrecord points to the token list `'u1'`, i.e., the template preceding the `#` for column 1.

(2) T<sub>E</sub>X now looks at what follows the `\cr` that ended the preamble. It is not `'\noalign'` or `'\omit'`, so this input is put back to be read again, and the template `'u1'` is fed to the scanner. Just before reading `'u1'`, T<sub>E</sub>X goes into restricted horizontal mode. Just after reading `'u1'`, T<sub>E</sub>X will see `'a1'`, and then (when the `&` is sensed) T<sub>E</sub>X will see `'v1'`. Then T<sub>E</sub>X scans an *endv* token, indicating the end of a column. At this point an *unset\_node* is created, containing the contents of the current hlist (i.e., `'u1a1v1'`). The natural width of this unset node replaces the *width* field of the alignrecord for column 1; in general, the alignrecords will record the maximum natural width that has occurred so far in a given column.

(3) Since `'\omit'` follows the `'&'`, the templates for column 2 are now bypassed. Again T<sub>E</sub>X goes into restricted horizontal mode and makes an *unset\_node* from the resulting hlist; but this time the hlist contains simply `'a2'`. The natural width of the new unset box is remembered in the *width* field of the alignrecord for column 2.

(4) A third *unset\_node* is created for column 3, using essentially the mechanism that worked for column 1; this unset box contains `'u3\vrule v3'`. The vertical rule in this case has running dimensions that will later

extend to the height and depth of the whole first row, since each *unset\_node* in a row will eventually inherit the height and depth of its enclosing box.

(5) The first row has now ended; it is made into a single unset box comprising the following seven items:

```
\glue 2pt plus 3pt
\unsetbox for 1 column: u1a1v1
\glue 2pt plus 3pt
\unsetbox for 1 column: a2
\glue 1pt plus 1fil
\unsetbox for 1 column: u3\vrule v3
\glue 1pt plus 1fil
```

The width of this unset row is unimportant, but it has the correct height and depth, so the correct baselineskip glue will be computed as the row is inserted into a vertical list.

(6) Since ‘\noalign’ follows the current \cr, T<sub>E</sub>X appends additional material (in this case \vskip 3pt) to the vertical list. While processing this material, T<sub>E</sub>X will be in internal vertical mode, and *no\_align\_group* will be on *save\_stack*.

(7) The next row produces an unset box that looks like this:

```
\glue 2pt plus 3pt
\unsetbox for 2 columns: u1b1v1u2b2v2
\glue 1pt plus 1fil
\unsetbox for 1 column: (empty)
\glue 1pt plus 1fil
```

The natural width of the unset box that spans columns 1 and 2 is stored in a “span node,” which we will explain later; the *info* field of the alignrecord for column 1 now points to the new span node, and the *info* of the span node points to *end\_span*.

(8) The final row produces the unset box

```
\glue 2pt plus 3pt
\unsetbox for 1 column: (empty)
\glue 2pt plus 3pt
\unsetbox for 2 columns: u2c2v2
\glue 1pt plus 1fil
```

A new span node is attached to the alignrecord for column 2.

(9) The last step is to compute the true column widths and to change all the unset boxes to hboxes, appending the whole works to the vertical list that encloses the \halign. The rules for deciding on the final widths of each unset column box will be explained below.

Note that as \halign is being processed, we fearlessly give up control to the rest of T<sub>E</sub>X. At critical junctures, an alignment routine is called upon to step in and do some little action, but most of the time these routines just lurk in the background. It’s something like post-hypnotic suggestion.

**780.** We have mentioned that alignrecords contain no *height* or *depth* fields. Their *glue\_sign* and *glue\_order* are pre-empted as well, since it is necessary to store information about what to do when a template ends. This information is called the *extra\_info* field.

```
define u_part(#) ≡ mem[# + height_offset].int { pointer to  $\langle u_j \rangle$  token list }
define v_part(#) ≡ mem[# + depth_offset].int { pointer to  $\langle v_j \rangle$  token list }
define extra_info(#) ≡ info(# + list_offset) { info to remember during template }
```

**781.** Alignments can occur within alignments, so a small stack is used to access the alignrecord information. At each level we have a *preamble* pointer, indicating the beginning of the preamble list; a *cur\_align* pointer, indicating the current position in the preamble list; a *cur\_span* pointer, indicating the value of *cur\_align* at the beginning of a sequence of spanned columns; a *cur\_loop* pointer, indicating the tabskip glue before an alignrecord that should be copied next if the current list is extended; and the *align\_state* variable, which indicates the nesting of braces so that `\cr` and `\span` and tab marks are properly intercepted. There also are pointers *cur\_head* and *cur\_tail* to the head and tail of a list of adjustments being moved out from horizontal mode to vertical mode.

The current values of these seven quantities appear in global variables; when they have to be pushed down, they are stored in 5-word nodes, and *align\_ptr* points to the topmost such node.

```
define preamble  $\equiv$  link(align_head) { the current preamble list }
define align_stack_node_size = 5 { number of mem words to save alignment states }
```

$\langle$  Global variables 13  $\rangle$  + $\equiv$

```
cur_align: pointer; { current position in preamble list }
cur_span: pointer; { start of currently spanned columns in preamble list }
cur_loop: pointer; { place to copy when extending a periodic preamble }
align_ptr: pointer; { most recently pushed-down alignment stack node }
cur_head, cur_tail: pointer; { adjustment list pointers }
```

**782.** The *align\_state* and *preamble* variables are initialized elsewhere.

$\langle$  Set initial values of key variables 21  $\rangle$  + $\equiv$

```
align_ptr  $\leftarrow$  null; cur_align  $\leftarrow$  null; cur_span  $\leftarrow$  null; cur_loop  $\leftarrow$  null; cur_head  $\leftarrow$  null;
cur_tail  $\leftarrow$  null;
```

**783.** Alignment stack maintenance is handled by a pair of trivial routines called *push\_alignment* and *pop\_alignment*.

**procedure** *push\_alignment*;

```
var p: pointer; { the new alignment stack node }
begin p  $\leftarrow$  get_node(align_stack_node_size); link(p)  $\leftarrow$  align_ptr; info(p)  $\leftarrow$  cur_align;
llink(p)  $\leftarrow$  preamble; rlink(p)  $\leftarrow$  cur_span; mem[p + 2].int  $\leftarrow$  cur_loop; mem[p + 3].int  $\leftarrow$  align_state;
info(p + 4)  $\leftarrow$  cur_head; link(p + 4)  $\leftarrow$  cur_tail; align_ptr  $\leftarrow$  p; cur_head  $\leftarrow$  get_avail;
end;
```

**procedure** *pop\_alignment*;

```
var p: pointer; { the top alignment stack node }
begin free_avail(cur_head); p  $\leftarrow$  align_ptr; cur_tail  $\leftarrow$  link(p + 4); cur_head  $\leftarrow$  info(p + 4);
align_state  $\leftarrow$  mem[p + 3].int; cur_loop  $\leftarrow$  mem[p + 2].int; cur_span  $\leftarrow$  rlink(p); preamble  $\leftarrow$  llink(p);
cur_align  $\leftarrow$  info(p); align_ptr  $\leftarrow$  link(p); free_node(p, align_stack_node_size);
end;
```

**784.** T<sub>E</sub>X has eight procedures that govern alignments: *init\_align* and *fin\_align* are used at the very beginning and the very end; *init\_row* and *fin\_row* are used at the beginning and end of individual rows; *init\_span* is used at the beginning of a sequence of spanned columns (possibly involving only one column); *init\_col* and *fin\_col* are used at the beginning and end of individual columns; and *align\_peek* is used after `\cr` to see whether the next item is `\noalign`.

We shall consider these routines in the order they are first used during the course of a complete `\halign`, namely *init\_align*, *align\_peek*, *init\_row*, *init\_span*, *init\_col*, *fin\_col*, *fin\_row*, *fin\_align*.

**785.** When `\halign` or `\valign` has been scanned in an appropriate mode, T<sub>E</sub>X calls `init_align`, whose task is to get everything off to a good start. This mostly involves scanning the preamble and putting its information into the preamble list.

```

⟨Declare the procedure called get_preamble_token 793⟩
procedure align_peek; forward;
procedure normal_paragraph; forward;
procedure init_align;
  label done, done1, done2, continue;
  var save_cs_ptr: pointer; { warning_index value for error messages }
    p: pointer; { for short-term temporary use }
  begin save_cs_ptr ← cur_cs; { \halign or \valign, usually }
  push_alignment; align_state ← -1000000; { enter a new alignment level }
  ⟨Check for improper alignment in displayed math 787⟩;
  push_nest; { enter a new semantic level }
  ⟨Change current mode to -vmode for \halign, -hmode for \valign 786⟩;
  scan_spec(align_group, false);
  ⟨Scan the preamble and record it in the preamble list 788⟩;
  new_save_level(align_group);
  if every_cr ≠ null then begin_token_list(every_cr, every_cr_text);
  align_peek; { look for \noalign or \omit }
end;

```

**786.** In vertical modes, `prev_depth` already has the correct value. But if we are in `mmode` (displayed formula mode), we reach out to the enclosing vertical mode for the `prev_depth` value that produces the correct baseline calculations.

```

⟨Change current mode to -vmode for \halign, -hmode for \valign 786⟩ ≡
  if mode = mmode then
    begin mode ← -vmode; prev_depth ← nest[nest_ptr - 2].aux_field.sc;
    end
  else if mode > 0 then negate(mode)

```

This code is used in section 785.

**787.** When `\halign` is used as a displayed formula, there should be no other pieces of mlists present.

```

⟨Check for improper alignment in displayed math 787⟩ ≡
  if (mode = mmode) ∧ ((tail ≠ head) ∨ (incomplete_noad ≠ null)) then
    begin print_err("Improper_"); print_esc("halign"); print("_inside_$$$'s");
    help3("Displays_can_use_special_alignments_(like_\\eqalignno)")
    ("only_if_nothing_but_the_alignment_itself_is_between_$$$'s.")
    ("So_I've_deleted_the_formulas_that_preceded_this_alignment."); error; flush_math;
    end

```

This code is used in section 785.

**788.**  $\langle$  Scan the preamble and record it in the *preamble* list 788  $\rangle \equiv$   
*preamble*  $\leftarrow$  *null*; *cur\_align*  $\leftarrow$  *align\_head*; *cur\_loop*  $\leftarrow$  *null*; *scanner\_status*  $\leftarrow$  *aligning*;  
*warning\_index*  $\leftarrow$  *save\_cs\_ptr*; *align\_state*  $\leftarrow$  -1000000; { at this point, *cur\_cmd* = *left\_brace* }  
**loop begin**  $\langle$  Append the current tabskip glue to the preamble list 789  $\rangle$ ;  
  **if** *cur\_cmd* = *car\_ret* **then goto** *done*; {  $\backslash$ cr ends the preamble }  
   $\langle$  Scan preamble text until *cur\_cmd* is *tab\_mark* or *car\_ret*, looking for changes in the tabskip glue;  
  append an alignrecord to the preamble list 790  $\rangle$ ;  
**end**;

*done*: *scanner\_status*  $\leftarrow$  *normal*

This code is used in section 785.

**789.**  $\langle$  Append the current tabskip glue to the preamble list 789  $\rangle \equiv$   
*link*(*cur\_align*)  $\leftarrow$  *new\_param\_glue*(*tab\_skip\_code*); *cur\_align*  $\leftarrow$  *link*(*cur\_align*)

This code is used in section 788.

**790.**  $\langle$  Scan preamble text until *cur\_cmd* is *tab\_mark* or *car\_ret*, looking for changes in the tabskip glue;  
append an alignrecord to the preamble list 790  $\rangle \equiv$   
 $\langle$  Scan the template  $\langle u_j \rangle$ , putting the resulting token list in *hold\_head* 794  $\rangle$ ;  
*link*(*cur\_align*)  $\leftarrow$  *new\_null\_box*; *cur\_align*  $\leftarrow$  *link*(*cur\_align*); { a new alignrecord }  
*info*(*cur\_align*)  $\leftarrow$  *end\_span*; *width*(*cur\_align*)  $\leftarrow$  *null\_flag*; *u\_part*(*cur\_align*)  $\leftarrow$  *link*(*hold\_head*);  
 $\langle$  Scan the template  $\langle v_j \rangle$ , putting the resulting token list in *hold\_head* 795  $\rangle$ ;  
*v\_part*(*cur\_align*)  $\leftarrow$  *link*(*hold\_head*)

This code is used in section 788.

**791.** We enter  $\backslash$ span into *eqtb* with *tab\_mark* as its command code, and with *span\_code* as the command modifier. This makes T<sub>E</sub>X interpret it essentially the same as an alignment delimiter like  $\&$ , yet it is recognizably different when we need to distinguish it from a normal delimiter. It also turns out to be useful to give a special *cr\_code* to  $\backslash$ cr, and an even larger *cr\_cr\_code* to  $\backslash$ cr cr.

The end of a template is represented by two “frozen” control sequences called  $\backslash$ endtemplate. The first has the command code *end\_template*, which is  $>$  *outer\_call*, so it will not easily disappear in the presence of errors. The *get\_x\_token* routine converts the first into the second, which has *endv* as its command code.

```
define span_code = 256 { distinct from any character }
define cr_code = 257 { distinct from span_code and from any character }
define cr_cr_code = cr_code + 1 { this distinguishes  $\backslash$ cr cr from  $\backslash$ cr }
define end_template_token  $\equiv$  cs_token_flag + frozen_end_template
```

$\langle$  Put each of T<sub>E</sub>X’s primitives into the hash table 232  $\rangle + \equiv$

```
primitive("span", tab_mark, span_code);
primitive("cr", car_ret, cr_code); text(frozen_cr)  $\leftarrow$  "cr"; eqtb[frozen_cr]  $\leftarrow$  eqtb[cur_val];

This code is used in section 790.

**796.** The tricky part about alignments is getting the templates into the scanner at the right time, and recovering control when a row or column is finished.

We usually begin a row after each `\cr` has been sensed, unless that `\cr` is followed by `\noalign` or by the right brace that terminates the alignment. The *align\_peek* routine is used to look ahead and do the right thing; it either gets a new row started, or gets a `\noalign` started, or finishes off the alignment.

$\langle$  Declare the procedure called *align\_peek* 796  $\rangle \equiv$   
**procedure** *align\_peek*;  
  **label** *restart*;  
  **begin** *restart*:  $align\_state \leftarrow 1000000$ ;  $\langle$  Get the next non-blank non-call token 417  $\rangle$ ;  
  **if**  $cur\_cmd = no\_align$  **then**  
    **begin** *scan\_left\_brace*; *new\_save\_level*(*no\_align\_group*);  
    **if**  $mode = -vmode$  **then** *normal\_paragraph*;  
  **end**  
  **else if**  $cur\_cmd = right\_brace$  **then** *fin\_align*  
    **else if** ( $cur\_cmd = car\_ret$ )  $\wedge$  ( $cur\_chr = cr\_cr\_code$ ) **then goto** *restart* { ignore `\cr cr` }  
    **else begin** *init\_row*; { start a new row }  
      *init\_col*; { start a new column and replace what we peeked at }  
    **end**;  
  **end**;

This code is used in section 811.

**797.** To start a row (i.e., a ‘row’ that rhymes with ‘dough’ but not with ‘bough’), we enter a new semantic level, copy the first *tabskip* glue, and change from internal vertical mode to restricted horizontal mode or vice versa. The *space\_factor* and *prev\_depth* are not used on this semantic level, but we clear them to zero just to be tidy.

$\langle$  Declare the procedure called *init\_span* 798  $\rangle$   
**procedure** *init\_row*;  
  **begin** *push\_nest*;  $mode \leftarrow (-hmode - vmode) - mode$ ;  
  **if**  $mode = -hmode$  **then**  $space\_factor \leftarrow 0$  **else**  $prev\_depth \leftarrow 0$ ;  
  *tail\_append*(*new\_glue*(*glue\_ptr*(*preamble*)));  $subtype(tail) \leftarrow tab\_skip\_code + 1$ ;  
   $cur\_align \leftarrow link(preamble)$ ;  $cur\_tail \leftarrow cur\_head$ ; *init\_span*(*cur\_align*);  
  **end**;

**798.** The parameter to *init\_span* is a pointer to the alignrecord where the next column or group of columns will begin. A new semantic level is entered, so that the columns will generate a list for subsequent packaging.

```

⟨Declare the procedure called init_span 798⟩ ≡
procedure init_span(p : pointer);
  begin push_nest;
  if mode = -hmode then space_factor ← 1000
  else begin prev_depth ← ignore_depth; normal_paragraph;
    end;
  cur_span ← p;
  end;

```

This code is used in section 797.

**799.** When a column begins, we assume that *cur\_cmd* is either *omit* or else the current token should be put back into the input until the  $\langle u_j \rangle$  template has been scanned. (Note that *cur\_cmd* might be *tab\_mark* or *car\_ret*.) We also assume that *align\_state* is approximately 1000000 at this time. We remain in the same mode, and start the template if it is called for.

```

procedure init_col;
  begin extra_info(cur_align) ← cur_cmd;
  if cur_cmd = omit then align_state ← 0
  else begin back_input; begin_token_list(u_part(cur_align), u_template);
    end; { now align_state = 1000000 }
  end;

```

**800.** The scanner sets *align\_state* to zero when the  $\langle u_j \rangle$  template ends. When a subsequent  $\backslash cr$  or  $\backslash span$  or tab mark occurs with *align\_state* = 0, the scanner activates the following code, which fires up the  $\langle v_j \rangle$  template. We need to remember the *cur\_chr*, which is either *cr\_cr\_code*, *cr\_code*, *span\_code*, or a character code, depending on how the column text has ended.

This part of the program had better not be activated when the preamble to another alignment is being scanned, or when no alignment preamble is active.

```

⟨Insert the  $\langle v_j \rangle$  template and goto restart 800⟩ ≡
  begin if (scanner_status = aligning) ∨ (cur_align = null) then
    fatal_error("(interwoven_alignment_preambles_are_not_allowed)");
    cur_cmd ← extra_info(cur_align); extra_info(cur_align) ← cur_chr;
    if cur_cmd = omit then begin_token_list(omit_template, v_template)
    else begin_token_list(v_part(cur_align), v_template);
    align_state ← 1000000; goto restart;
  end

```

This code is used in section 348.

**801.** The token list *omit\_template* just referred to is a constant token list that contains the special control sequence  $\backslash endtemplate$  only.

```

⟨Initialize the special list heads and constant nodes 801⟩ ≡
  info(omit_template) ← end_template_token; { link(omit_template) = null }

```

See also sections 808, 831, 992, and 999.

This code is used in section 170.

**802.** When the *endv* command at the end of a  $\langle v_j \rangle$  template comes through the scanner, things really start to happen; and it is the *fin\_col* routine that makes them happen. This routine returns *true* if a row as well as a column has been finished.

```

function fin_col: boolean;
  label exit;
  var p: pointer; { the alignrecord after the current one }
      q,r: pointer; { temporary pointers for list manipulation }
      s: pointer; { a new span node }
      u: pointer; { a new unset box }
      w: scaled; { natural width }
      o: glue_ord; { order of infinity }
      n: halfword; { span counter }
  begin if cur_align = null then confusion("endv");
  q ← link(cur_align); if q = null then confusion("endv");
  if align_state < 500000 then fatal_error("(interwoven_alignment_preambles_are_not_allowed)");
  p ← link(q);  $\langle$ If the preamble list has been traversed, check that the row has ended 803 $\rangle$ ;
  if extra_info(cur_align) ≠ span_code then
    begin unsave; new_save_level(align_group);
     $\langle$ Package an unset box for the current column and record its width 807 $\rangle$ ;
     $\langle$ Copy the tabskip glue between columns 806 $\rangle$ ;
    if extra_info(cur_align) ≥ cr_code then
      begin fin_col ← true; return;
    end;
    init_span(p);
    end;
  align_state ← 1000000;  $\langle$ Get the next non-blank non-call token 417 $\rangle$ ;
  cur_align ← p; init_col; fin_col ← false;
exit: end;

```

**803.**  $\langle$ If the preamble list has been traversed, check that the row has ended 803 $\rangle$  ≡

```

if (p = null) ∧ (extra_info(cur_align) < cr_code) then
  if cur_loop ≠ null then  $\langle$ Lengthen the preamble periodically 804 $\rangle$ 
  else begin print_err("Extra_alignment_tab_has_been_changed_to_"); print_esc("cr");
    help3("You_have_given_more_\span_or_\&marks_than_there_were")
    ("in_the_preamble_to_the_\halign_or_\valign_now_in_progress.")

 $glue\_sign(u) \leftarrow o; glue\_shrink(u) \leftarrow total\_shrink[o];$   
 $pop\_nest; link(tail) \leftarrow u; tail \leftarrow u;$   
**end**

This code is used in section 802.

**808.** A span node is a 2-word record containing *width*, *info*, and *link* fields. The *link* field is not really a link, it indicates the number of spanned columns; the *info* field points to a span node for the same starting column, having a greater extent of spanning, or to *end\_span*, which has the largest possible *link* field; the *width* field holds the largest natural width corresponding to a particular set of spanned columns.

A list of the maximum widths so far, for spanned columns starting at a given column, begins with the *info* field of the alignrecord for that column.

**define**  $span\_node\_size = 2$   $\{ \text{number of } mem \text{ words for a span node} \}$   
 $\langle$  Initialize the special list heads and constant nodes 801  $\rangle + \equiv$   
 $link(end\_span) \leftarrow max\_quarterword + 1; info(end\_span) \leftarrow null;$

```

809.  ⟨Update width entry for spanned columns 809⟩ ≡
  begin  $q \leftarrow cur\_span$ ;
  repeat  $incr(n)$ ;  $q \leftarrow link(link(q))$ ;
  until  $q = cur\_align$ ;
  if  $n > max\_quarterword$  then  $confusion("256\_spans")$ ; { this can happen, but won't }
   $q \leftarrow cur\_span$ ;
  while  $link(info(q)) < n$  do  $q \leftarrow info(q)$ ;
  if  $link(info(q)) > n$  then
    begin  $s \leftarrow get\_node(span\_node\_size)$ ;  $info(s) \leftarrow info(q)$ ;  $link(s) \leftarrow n$ ;  $info(q) \leftarrow s$ ;  $width(s) \leftarrow w$ ;
    end
  else if  $width(info(q)) < w$  then  $width(info(q)) \leftarrow w$ ;
  end

```

This code is used in section 807.

**810.** At the end of a row, we append an unset box to the current vlist (for `\halign`) or the current hlist (for `\valign`). This unset box contains the unset boxes for the columns, separated by the `tabskip` glue. Everything will be set later.

```

procedure  $fin\_row$ ;
  var  $p$ : pointer; { the new unset box }
  begin if  $mode = -hmode$  then
    begin  $adjust\_hlist(head, false)$ ;  $delete\_glue\_ref(cur\_kanji\_skip)$ ;  $delete\_glue\_ref(cur\_xkanji\_skip)$ ;
     $cur\_kanji\_skip \leftarrow space\_ptr(head)$ ;  $cur\_xkanji\_skip \leftarrow xspace\_ptr(head)$ ;  $add\_glue\_ref(cur\_kanji\_skip)$ ;
     $add\_glue\_ref(cur\_xkanji\_skip)$ ;  $p \leftarrow hpack(link(head), natural)$ ;  $pop\_nest$ ;  $append\_to\_vlist(p)$ ;
    if  $cur\_head \neq cur\_tail$  then
      begin  $link(tail) \leftarrow link(cur\_head)$ ;  $tail \leftarrow cur\_tail$ ;
      end;
    end
  else begin  $p \leftarrow vpack(link(head), natural)$ ;  $pop\_nest$ ;  $link(tail) \leftarrow p$ ;  $tail \leftarrow p$ ;  $space\_factor \leftarrow 1000$ ;
  end;
   $type(p) \leftarrow unset\_node$ ;  $glue\_stretch(p) \leftarrow 0$ ;
  if  $every\_cr \neq null$  then  $begin\_token\_list(every\_cr, every\_cr\_text)$ ;
   $align\_peek$ ;
  end; { note that  $glue\_shrink(p) = 0$  since  $glue\_shrink \equiv shift\_amount$  }

```

**811.** Finally, we will reach the end of the alignment, and we can breathe a sigh of relief that memory hasn't overflowed. All the unset boxes will now be set so that the columns line up, taking due account of spanned columns.

```

procedure do_assignments; forward;
procedure resume_after_display; forward;
procedure build_page; forward;
procedure fin_align;
  var p, q, r, s, u, v, z: pointer; { registers for the list operations }
  t, w: scaled; { width of column }
  o: scaled; { shift offset for unset boxes }
  n: halfword; { matching span amount }
  rule_save: scaled; { temporary storage for overflow_rule }
  aux_save: memory_word; { temporary storage for aux }
  begin if cur_group  $\neq$  align_group then confusion("align1");
  unsave; { that align_group was for individual entries }
  if cur_group  $\neq$  align_group then confusion("align0");
  unsave; { that align_group was for the whole alignment }
  if nest[nest_ptr - 1].mode_field = mmode then o  $\leftarrow$  display_indent
  else o  $\leftarrow$  0;
  < Go through the preamble list, determining the column widths and changing the alignrecords to dummy
  unset boxes 812 >;
  < Package the preamble list, to determine the actual tabskip glue amounts, and let p point to this
  prototype box 815 >;
  < Set the glue in all the unset boxes of the current list 816 >;
  flush_node_list(p); pop_alignment; < Insert the current list into its environment 823 >;
  end;
< Declare the procedure called align_peek 796 >

```

**812.** It's time now to dismantle the preamble list and to compute the column widths. Let  $w_{ij}$  be the maximum of the natural widths of all entries that span columns  $i$  through  $j$ , inclusive. The alignrecord for column  $i$  contains  $w_{ii}$  in its *width* field, and there is also a linked list of the nonzero  $w_{ij}$  for increasing  $j$ , accessible via the *info* field; these span nodes contain the value  $j - i + \text{min\_quarterword}$  in their *link* fields. The values of  $w_{ii}$  were initialized to *null\_flag*, which we regard as  $-\infty$ .

The final column widths are defined by the formula

$$w_j = \max_{1 \leq i \leq j} \left( w_{ij} - \sum_{i \leq k < j} (t_k + w_k) \right),$$

where  $t_k$  is the natural width of the tabskip glue between columns  $k$  and  $k + 1$ . However, if  $w_{ij} = -\infty$  for all  $i$  in the range  $1 \leq i \leq j$  (i.e., if every entry that involved column  $j$  also involved column  $j + 1$ ), we let  $w_j = 0$ , and we zero out the tabskip glue after column  $j$ .

T<sub>E</sub>X computes these values by using the following scheme: First  $w_1 = w_{11}$ . Then replace  $w_{2j}$  by  $\max(w_{2j}, w_{1j} - t_1 - w_1)$ , for all  $j > 1$ . Then  $w_2 = w_{22}$ . Then replace  $w_{3j}$  by  $\max(w_{3j}, w_{2j} - t_2 - w_2)$  for all  $j > 2$ ; and so on. If any  $w_j$  turns out to be  $-\infty$ , its value is changed to zero and so is the next tabskip.

```

⟨ Go through the preamble list, determining the column widths and changing the alignrecords to dummy
  unset boxes 812 ⟩ ≡
  q ← link(preamble);
  repeat flush_list(u_part(q)); flush_list(v_part(q)); p ← link(link(q));
    if width(q) = null_flag then ⟨ Nullify width(q) and the tabskip glue following this column 813 ⟩;
    if info(q) ≠ end_span then
      ⟨ Merge the widths in the span nodes of q with those of p, destroying the span nodes of q 814 ⟩;
      type(q) ← unset_node; span_count(q) ← min_quarterword; height(q) ← 0; depth(q) ← 0;
      glue_order(q) ← normal; glue_sign(q) ← normal; glue_stretch(q) ← 0; glue_shrink(q) ← 0; q ← p;
  until q = null

```

This code is used in section 811.

```

813. ⟨ Nullify width(q) and the tabskip glue following this column 813 ⟩ ≡
  begin width(q) ← 0; r ← link(q); s ← glue_ptr(r);
  if s ≠ zero_glue then
    begin add_glue_ref(zero_glue); delete_glue_ref(s); glue_ptr(r) ← zero_glue;
    end;
  end

```

This code is used in section 812.

**814.** Merging of two span-node lists is a typical exercise in the manipulation of linearly linked data structures. The essential invariant in the following **repeat** loop is that we want to dispense with node  $r$ , in  $q$ 's list, and  $u$  is its successor; all nodes of  $p$ 's list up to and including  $s$  have been processed, and the successor of  $s$  matches  $r$  or precedes  $r$  or follows  $r$ , according as  $link(r) = n$  or  $link(r) > n$  or  $link(r) < n$ .

⟨Merge the widths in the span nodes of  $q$  with those of  $p$ , destroying the span nodes of  $q$  814⟩ ≡

```

begin  $t \leftarrow width(q) + width(glue\_ptr(link(q)))$ ;  $r \leftarrow info(q)$ ;  $s \leftarrow end\_span$ ;  $info(s) \leftarrow p$ ;
 $n \leftarrow min\_quarterword + 1$ ;
repeat  $width(r) \leftarrow width(r) - t$ ;  $u \leftarrow info(r)$ ;
  while  $link(r) > n$  do
    begin  $s \leftarrow info(s)$ ;  $n \leftarrow link(info(s)) + 1$ ;
    end;
  if  $link(r) < n$  then
    begin  $info(r) \leftarrow info(s)$ ;  $info(s) \leftarrow r$ ;  $decr(link(r))$ ;  $s \leftarrow r$ ;
    end
  else begin if  $width(r) > width(info(s))$  then  $width(info(s)) \leftarrow width(r)$ ;
     $free\_node(r, span\_node\_size)$ ;
  end;
   $r \leftarrow u$ ;
until  $r = end\_span$ ;
end

```

This code is used in section 812.

**815.** Now the preamble list has been converted to a list of alternating unset boxes and tabskip glue, where the box widths are equal to the final column sizes. In case of `\valign`, we change the widths to heights, so that a correct error message will be produced if the alignment is overfull or underfull.

⟨Package the preamble list, to determine the actual tabskip glue amounts, and let  $p$  point to this prototype box 815⟩ ≡

```

**823.** We now have a completed alignment, in the list that starts at *head* and ends at *tail*. This list will be merged with the one that encloses it. (In case the enclosing mode is *mmode*, for displayed formulas, we will need to insert glue before and after the display; that part of the program will be deferred until we're more familiar with such operations.)

In restricted horizontal mode, the *clang* part of *aux* is undefined; an over-cautious Pascal runtime system may complain about this.

```

⟨Insert the current list into its environment 823⟩ ≡
  aux_save ← aux; p ← link(head); q ← tail; pop_nest;
  if mode = mmode then ⟨Finish an alignment in a display 1218⟩
  else begin aux ← aux_save; link(tail) ← p;
    if p ≠ null then tail ← q;
    if mode = vmode then build_page;
  end

```

This code is used in section 811.

**824. Breaking paragraphs into lines.** We come now to what is probably the most interesting algorithm of T<sub>E</sub>X: the mechanism for choosing the “best possible” breakpoints that yield the individual lines of a paragraph. T<sub>E</sub>X’s line-breaking algorithm takes a given horizontal list and converts it to a sequence of boxes that are appended to the current vertical list. In the course of doing this, it creates a special data structure containing three kinds of records that are not used elsewhere in T<sub>E</sub>X. Such nodes are created while a paragraph is being processed, and they are destroyed afterwards; thus, the other parts of T<sub>E</sub>X do not need to know anything about how line-breaking is done.

The method used here is based on an approach devised by Michael F. Plass and the author in 1977, subsequently generalized and improved by the same two people in 1980. A detailed discussion appears in *SOFTWARE—Practice & Experience* **11** (1981), 1119–1184, where it is shown that the line-breaking problem can be regarded as a special case of the problem of computing the shortest path in an acyclic network. The cited paper includes numerous examples and describes the history of line breaking as it has been practiced by printers through the ages. The present implementation adds two new ideas to the algorithm of 1980: Memory space requirements are considerably reduced by using smaller records for inactive nodes than for active ones, and arithmetic overflow is avoided by using “delta distances” instead of keeping track of the total distance from the beginning of the paragraph to the current point.

**825.** The *line\_break* procedure should be invoked only in horizontal mode; it leaves that mode and places its output into the current vlist of the enclosing vertical mode (or internal vertical mode). There is one explicit parameter: *final\_widow\_penalty* is the amount of additional penalty to be inserted before the final line of the paragraph.

There are also a number of implicit parameters: The hlist to be broken starts at *link(head)*, and it is nonempty. The value of *prev\_graf* in the enclosing semantic level tells where the paragraph should begin in the sequence of line numbers, in case hanging indentation or `\parshape` are in use; *prev\_graf* is zero unless this paragraph is being continued after a displayed formula. Other implicit parameters, such as the *par\_shape\_ptr* and various penalties to use for hyphenation, etc., appear in *eqtb*.

After *line\_break* has acted, it will have updated the current vlist and the value of *prev\_graf*. Furthermore, the global variable *just\_box* will point to the final box created by *line\_break*, so that the width of this line can be ascertained when it is necessary to decide whether to use *above\_display\_skip* or *above\_display\_short\_skip* before a displayed formula.

⟨Global variables 13⟩ +≡  
*just\_box*: pointer; { the *hlist\_node* for the last line of the new paragraph }

**826.** Since *line\_break* is a rather lengthy procedure—sort of a small world unto itself—we must build it up little by little, somewhat more cautiously than we have done with the simpler procedures of T<sub>E</sub>X. Here is the general outline.

⟨Declare subprocedures for *line\_break* 837⟩  
**procedure** *line\_break*(*final\_widow\_penalty* : integer);  
  **label** *done*, *done1*, *done2*, *done3*, *done4*, *done5*, *continue*;  
  **var** ⟨Local variables for line breaking 873⟩  
  **begin** *pack\_begin\_line* ← *mode\_line*; { this is for over/underfull box messages }  
  ⟨Get ready to start line breaking 827⟩;  
  ⟨Find optimal breakpoints 874⟩;  
  ⟨Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and  
  append them to the current vertical list 887⟩;  
  ⟨Clean up the memory by removing the break nodes 876⟩;  
  *pack\_begin\_line* ← 0;  
  **end**;

**827.** The first task is to move the list from *head* to *temp\_head* and go into the enclosing semantic level. We also append the `\parfillskip` glue to the end of the paragraph, removing a space (or other glue node) if it was there, since spaces usually precede blank lines and instances of ‘`$$$`’. The *par\_fill\_skip* is preceded by an infinite penalty, so it will never be considered as a potential breakpoint.

This code assumes that a *glue\_node* and a *penalty\_node* occupy the same number of *mem* words.

```

⟨Get ready to start line breaking 827⟩ ≡
  first_use ← true; chain ← false; delete_glue_ref(cur_kanji_skip); delete_glue_ref(cur_xkanji_skip);
  cur_kanji_skip ← space_ptr(head); cur_xkanji_skip ← xspace_ptr(head); add_glue_ref(cur_kanji_skip);
  add_glue_ref(cur_xkanji_skip); link(temp_head) ← link(head);
  if ¬is_char_node(tail) ∧ (type(tail) = disp_node) then
    begin free_node(tail, small_node_size); tail ← prev_node; link(tail) ← null
    end;
  if is_char_node(tail) then tail_append(new_penalty(inf_penalty))
  else if type(tail) ≠ glue_node then tail_append(new_penalty(inf_penalty))
    else begin type(tail) ← penalty_node; delete_glue_ref(glue_ptr(tail)); flush_node_list(leader_ptr(tail));
           penalty(tail) ← inf_penalty;
    end;
  link(tail) ← new_param_glue(par_fill_skip_code); init_cur_lang ← prev_graf mod '200000;
  init_l_hyf ← prev_graf div '2000000; init_r_hyf ← (prev_graf div '200000) mod '100; pop_nest;

```

See also sections 838, 845, and 859.

This code is used in section 826.

**828.** When looking for optimal line breaks, T<sub>E</sub>X creates a “break node” for each break that is *feasible*, in the sense that there is a way to end a line at the given place without requiring any line to stretch more than a given tolerance. A break node is characterized by three things: the position of the break (which is a pointer to a *glue\_node*, *math\_node*, *penalty\_node*, or *disc\_node*); the ordinal number of the line that will follow this breakpoint; and the fitness classification of the line that has just ended, i.e., *tight\_fit*, *decent\_fit*, *loose\_fit*, or *very\_loose\_fit*.

```

define tight_fit = 3 {fitness classification for lines shrinking 0.5 to 1.0 of their shrinkability }
define loose_fit = 1 {fitness classification for lines stretching 0.5 to 1.0 of their stretchability }
define very_loose_fit = 0 {fitness classification for lines stretching more than their stretchability }
define decent_fit = 2 {fitness classification for all other lines }

```

**829.** The algorithm essentially determines the best possible way to achieve each feasible combination of position, line, and fitness. Thus, it answers questions like, “What is the best way to break the opening part of the paragraph so that the fourth line is a tight line ending at such-and-such a place?” However, the fact that all lines are to be the same length after a certain point makes it possible to regard all sufficiently large line numbers as equivalent, when the looseness parameter is zero, and this makes it possible for the algorithm to save space and time.

An “active node” and a “passive node” are created in *mem* for each feasible breakpoint that needs to be considered. Active nodes are three words long and passive nodes are two words long. We need active nodes only for breakpoints near the place in the paragraph that is currently being examined, so they are recycled within a comparatively short time after they are created.

**830.** An active node for a given breakpoint contains six fields:

*link* points to the next node in the list of active nodes; the last active node has *link* = *last\_active*.

*break\_node* points to the passive node associated with this breakpoint.

*line\_number* is the number of the line that follows this breakpoint.

*fitness* is the fitness classification of the line ending at this breakpoint.

*type* is either *hyphenated* or *unhyphenated*, depending on whether this breakpoint is a *disc\_node*.

*total\_demerits* is the minimum possible sum of demerits over all lines leading from the beginning of the paragraph to this breakpoint.

The value of *link* (*active*) points to the first active node on a linked list of all currently active nodes. This list is in order by *line\_number*, except that nodes with *line\_number* > *easy\_line* may be in any order relative to each other.

```

define active_node_size = 3 { number of words in active nodes }
define fitness ≡ subtype { very_loose_fit . . tight_fit on final line for this break }
define break_node ≡ rlink { pointer to the corresponding passive node }
define line_number ≡ llink { line that begins at this breakpoint }
define total_demerits(#) ≡ mem[# + 2].int { the quantity that TEX minimizes }
define unhyphenated = 0 { the type of a normal active break node }
define hyphenated = 1 { the type of an active node that breaks at a disc_node }
define last_active ≡ active { the active list ends where it begins }

```

**831.** ⟨ Initialize the special list heads and constant nodes 801 ⟩ +≡  
*type*(*last\_active*) ← *hyphenated*; *line\_number*(*last\_active*) ← *max\_halfword*; *subtype*(*last\_active*) ← 0;  
 { the *subtype* is never examined by the algorithm }

**832.** The passive node for a given breakpoint contains only four fields:

*link* points to the passive node created just before this one, if any, otherwise it is *null*.

*cur\_break* points to the position of this breakpoint in the horizontal list for the paragraph being broken.

*prev\_break* points to the passive node that should precede this one in an optimal path to this breakpoint.

*serial* is equal to *n* if this passive node is the *n*th one created during the current pass. (This field is used only when printing out detailed statistics about the line-breaking calculations.)

There is a global variable called *passive* that points to the most recently created passive node. Another global variable, *printed\_node*, is used to help print out the paragraph when detailed information about the line-breaking computation is being displayed.

```

define passive_node_size = 2 { number of words in passive nodes }
define cur_break ≡ rlink { in passive node, points to position of this breakpoint }
define prev_break ≡ llink { points to passive node that should precede this one }
define serial ≡ info { serial number for symbolic identification }

```

⟨ Global variables 13 ⟩ +≡

*passive*: *pointer*; { most recent node on passive list }

*printed\_node*: *pointer*; { most recent node that has been printed }

*pass\_number*: *halfword*; { the number of passive nodes allocated on this pass }

**833.** The active list also contains “delta” nodes that help the algorithm compute the badness of individual lines. Such nodes appear only between two active nodes, and they have *type* = *delta\_node*. If *p* and *r* are active nodes and if *q* is a delta node between them, so that *link*(*p*) = *q* and *link*(*q*) = *r*, then *q* tells the space difference between lines in the horizontal list that start after breakpoint *p* and lines that start after breakpoint *r*. In other words, if we know the length of the line that starts after *p* and ends at our current position, then the corresponding length of the line that starts after *r* is obtained by adding the amounts in node *q*. A delta node contains six scaled numbers, since it must record the net change in glue stretchability with respect to all orders of infinity. The natural width difference appears in *mem*[*q* + 1].*sc*; the stretch differences in units of pt, fil, fill, and fill appear in *mem*[*q* + 2 .. *q* + 5].*sc*; and the shrink difference appears in *mem*[*q* + 6].*sc*. The *subtype* field of a delta node is not used.

```
define delta_node_size = 7 { number of words in a delta node }
define delta_node = 2 { type field in a delta node }
```

**834.** As the algorithm runs, it maintains a set of six delta-like registers for the length of the line following the first active breakpoint to the current position in the given hlist. When it makes a pass through the active list, it also maintains a similar set of six registers for the length following the active breakpoint of current interest. A third set holds the length of an empty line (namely, the sum of `\leftskip` and `\rightskip`); and a fourth set is used to create new delta nodes.

When we pass a delta node we want to do operations like

```
for k ← 1 to 6 do cur_active_width[k] ← cur_active_width[k] + mem[q + k].sc;
```

and we want to do this without the overhead of **for** loops. The *do\_all\_six* macro makes such six-tuples convenient.

```
define do_all_six(#) ≡ #(1); #(2); #(3); #(4); #(5); #(6)
⟨Global variables 13⟩ +≡
active_width: array [1 .. 6] of scaled; { distance from first active node to cur_p }
cur_active_width: array [1 .. 6] of scaled; { distance from current active node }
background: array [1 .. 6] of scaled; { length of an “empty” line }
break_width: array [1 .. 6] of scaled; { length being computed after current break }
```

**835.** Let's state the principles of the delta nodes more precisely and concisely, so that the following programs will be less obscure. For each legal breakpoint  $p$  in the paragraph, we define two quantities  $\alpha(p)$  and  $\beta(p)$  such that the length of material in a line from breakpoint  $p$  to breakpoint  $q$  is  $\gamma + \beta(q) - \alpha(p)$ , for some fixed  $\gamma$ . Intuitively,  $\alpha(p)$  and  $\beta(q)$  are the total length of material from the beginning of the paragraph to a point "after" a break at  $p$  and to a point "before" a break at  $q$ ; and  $\gamma$  is the width of an empty line, namely the length contributed by `\leftskip` and `\rightskip`.

Suppose, for example, that the paragraph consists entirely of alternating boxes and glue skips; let the boxes have widths  $x_1 \dots x_n$  and let the skips have widths  $y_1 \dots y_n$ , so that the paragraph can be represented by  $x_1 y_1 \dots x_n y_n$ . Let  $p_i$  be the legal breakpoint at  $y_i$ ; then  $\alpha(p_i) = x_1 + y_1 + \dots + x_i + y_i$ , and  $\beta(p_i) = x_1 + y_1 + \dots + x_i$ . To check this, note that the length of material from  $p_2$  to  $p_5$ , say, is  $\gamma + x_3 + y_3 + x_4 + y_4 + x_5 = \gamma + \beta(p_5) - \alpha(p_2)$ .

The quantities  $\alpha$ ,  $\beta$ ,  $\gamma$  involve glue stretchability and shrinkability as well as a natural width. If we were to compute  $\alpha(p)$  and  $\beta(p)$  for each  $p$ , we would need multiple precision arithmetic, and the multiprecise numbers would have to be kept in the active nodes. T<sub>E</sub>X avoids this problem by working entirely with relative differences or "deltas." Suppose, for example, that the active list contains  $a_1 \delta_1 a_2 \delta_2 a_3$ , where the  $a$ 's are active breakpoints and the  $\delta$ 's are delta nodes. Then  $\delta_1 = \alpha(a_1) - \alpha(a_2)$  and  $\delta_2 = \alpha(a_2) - \alpha(a_3)$ . If the line breaking algorithm is currently positioned at some other breakpoint  $p$ , the *active\_width* array contains the value  $\gamma + \beta(p) - \alpha(a_1)$ . If we are scanning through the list of active nodes and considering a tentative line that runs from  $a_2$  to  $p$ , say, the *cur\_active\_width* array will contain the value  $\gamma + \beta(p) - \alpha(a_2)$ . Thus, when we move from  $a_2$  to  $a_3$ , we want to add  $\alpha(a_2) - \alpha(a_3)$  to *cur\_active\_width*; and this is just  $\delta_2$ , which appears in the active list between  $a_2$  and  $a_3$ . The *background* array contains  $\gamma$ . The *break\_width* array will be used to calculate values of new delta nodes when the active list is being updated.

**836.** Glue nodes in a horizontal list that is being paragraphed are not supposed to include "infinite" shrinkability; that is why the algorithm maintains four registers for stretching but only one for shrinking. If the user tries to introduce infinite shrinkability, the shrinkability will be reset to finite and an error message will be issued. A boolean variable *no\_shrink\_error\_yet* prevents this error message from appearing more than once per paragraph.

```
define check_shrinkage(#) ≡
  if (shrink_order(#) ≠ normal) ∧ (shrink(#) ≠ 0) then
    begin # ← finite_shrink(#);
  end
```

⟨Global variables 13⟩ +≡

```
no_shrink_error_yet: boolean; { have we complained about infinite shrinkage? }
```

**837.** ⟨Declare subprocedures for *line\_break* 837⟩ ≡

```
function finite_shrink(p: pointer): pointer; { recovers from infinite shrinkage }
  var q: pointer; { new glue specification }
  begin if no_shrink_error_yet then
    begin no_shrink_error_yet ← false; print_err("Infinite glue shrinkage found in a paragraph");
    help5("The paragraph just ended includes some glue that has")
    ("infinite shrinkability, e.g., \hskip 0pt minus 1fil.")

*background*[6]  $\leftarrow$  *shrink*(*q*) + *shrink*(*r*);

**839.** A pointer variable *cur\_p* runs through the given horizontal list as we look for breakpoints. This variable is global, since it is used both by *line\_break* and by its subprocedure *try\_break*.

Another global variable called *threshold* is used to determine the feasibility of individual lines: Breakpoints are feasible if there is a way to reach them without creating lines whose badness exceeds *threshold*. (The badness is compared to *threshold* before penalties are added, so that penalty values do not affect the feasibility of breakpoints, except that no break is allowed when the penalty is 10000 or more.) If *threshold* is 10000 or more, all legal breaks are considered feasible, since the *badness* function specified above never returns a value greater than 10000.

Up to three passes might be made through the paragraph in an attempt to find at least one set of feasible breakpoints. On the first pass, we have *threshold* = *pretolerance* and *second\_pass* = *final\_pass* = *false*. If this pass fails to find a feasible solution, *threshold* is set to *tolerance*, *second\_pass* is set *true*, and an attempt is made to hyphenate as many words as possible. If that fails too, we add *emergency\_stretch* to the background stretchability and set *final\_pass* = *true*.

$\langle$  Global variables 13  $\rangle +\equiv$   
*cur\_p*: *pointer*; { the current breakpoint under consideration }  
*chain*: *boolean*; { chain current line and next line? }  
*second\_pass*: *boolean*; { is this our second attempt to break this paragraph? }  
*final\_pass*: *boolean*; { is this our final attempt to break this paragraph? }  
*threshold*: *integer*; { maximum badness on feasible lines }

**840.** The heart of the line-breaking procedure is ‘*try\_break*’, a subroutine that tests if the current breakpoint *cur\_p* is feasible, by running through the active list to see what lines of text can be made from active nodes to *cur\_p*. If feasible breaks are possible, new break nodes are created. If *cur\_p* is too far from an active node, that node is deactivated.

The parameter *pi* to *try\_break* is the penalty associated with a break at *cur\_p*; we have *pi* = *eject\_penalty* if the break is forced, and *pi* = *inf\_penalty* if the break is illegal.

The other parameter, *break\_type*, is set to *hyphenated* or *unhyphenated*, depending on whether or not the current break is at a *disc\_node*. The end of a paragraph is also regarded as ‘*hyphenated*’; this case is distinguishable by the condition *cur\_p* = *null*.

     **begin**  $do\_all\_six(update\_width)$ ;  $prev\_prev\_r \leftarrow prev\_r$ ;  $prev\_r \leftarrow r$ ; **goto**  $continue$ ;  
     **end**

This code is used in section 840.

**844.** As we consider various ways to end a line at  $cur\_p$ , in a given line number class, we keep track of the best total demerits known, in an array with one entry for each of the fitness classifications. For example,  $minimal\_demerits[tight\_fit]$  contains the fewest total demerits of feasible line breaks ending at  $cur\_p$  with a  $tight\_fit$  line;  $best\_place[tight\_fit]$  points to the passive node for the break before  $cur\_p$  that achieves such an optimum; and  $best\_pl\_line[tight\_fit]$  is the  $line\_number$  field in the active node corresponding to  $best\_place[tight\_fit]$ . When no feasible break sequence is known, the  $minimal\_demerits$  entries will be equal to  $awful\_bad$ , which is  $2^{30} - 1$ . Another variable,  $minimum\_demerits$ , keeps track of the smallest value in the  $minimal\_demerits$  array.

**define**  $awful\_bad \equiv '7777777777$  { more than a billion demerits }  
 $\langle$  Global variables 13  $\rangle + \equiv$   
 $minimal\_demerits$ : **array** [ $very\_loose\_fit \dots tight\_fit$ ] **of**  $integer$ ;  
     { best total demerits known for current line class and position, given the fitness }  
 $minimum\_demerits$ :  $integer$ ; { best total demerits known for current line class and position }

**845.**  $\langle$  Get ready to start line breaking 827  $\rangle + \equiv$   
 $minimum\_demerits \leftarrow awful\_bad$ ;  $minimal\_demerits[tight\_fit] \leftarrow awful\_bad$ ;  
 $minimal\_demerits[decent\_fit] \leftarrow awful\_bad$ ;  $minimal\_demerits[loose\_fit] \leftarrow awful\_bad$ ;  
 $minimal\_demerits[very\_loose\_fit] \leftarrow awful\_bad$ ;

**846.** The first part of the following code is part of TEX's inner loop, so we don't want to waste any time. The current active node, namely node  $r$ , contains the line number that will be considered next. At the end of the list we have arranged the data structure so that  $r = last\_active$  and  $line\_number(last\_active) > old.l$ .

$\langle$  If a line number class has ended, create new active nodes for the best feasible breaks in that class; then  
**return** if  $r = last\_active$ , otherwise compute the new  $line\_width$  846  $\rangle \equiv$   
**begin**  $l \leftarrow line\_number(r)$ ;  
**if**  $l > old.l$  **then**  
     **begin** { now we are no longer in the inner loop }  
     **if**  $(minimum\_demerits < awful\_bad) \wedge ((old.l \neq easy\_line) \vee (r = last\_active))$  **then**  
          $\langle$  Create new active nodes for the best feasible breaks just found 847  $\rangle$ ;  
     **if**  $r = last\_active$  **then return**;  
      $\langle$  Compute the new line width 861  $\rangle$ ;  
     **end**;  
**end**

This code is used in section 840.

**847.** It is not necessary to create new active nodes having *minimal\_demerits* greater than *minimum\_demerits* +  $\mathbf{abs}(adj\_demerits)$ , since such active nodes will never be chosen in the final paragraph breaks. This observation allows us to omit a substantial number of feasible breakpoints from further consideration.

```

⟨ Create new active nodes for the best feasible breaks just found 847 ⟩ ≡
  begin if no_break_yet then ⟨ Compute the values of break_width 848 ⟩;
  ⟨ Insert a delta node to prepare for breaks at cur_p 854 ⟩;
  if  $\mathbf{abs}(adj\_demerits) \geq awful\_bad - minimum\_demerits}$  then minimum_demerits  $\leftarrow$  awful_bad - 1
  else minimum_demerits  $\leftarrow$  minimum_demerits +  $\mathbf{abs}(adj\_demerits)$ ;
  for fit_class  $\leftarrow$  very_loose_fit to tight_fit do
    begin if minimal_demerits[fit_class]  $\leq$  minimum_demerits then
      ⟨ Insert a new active node from best_place[fit_class] to cur_p 856 ⟩;
      minimal_demerits[fit_class]  $\leftarrow$  awful_bad;
    end;
  minimum_demerits  $\leftarrow$  awful_bad; ⟨ Insert a delta node to prepare for the next active node 855 ⟩;
end

```

This code is used in section 846.

**848.** When we insert a new active node for a break at  $cur\_p$ , suppose this new node is to be placed just before active node  $a$ ; then we essentially want to insert ‘ $\delta cur\_p \delta'$ ’ before  $a$ , where  $\delta = \alpha(a) - \alpha(cur\_p)$  and  $\delta' = \alpha(cur\_p) - \alpha(a)$  in the notation explained above. The  $cur\_active\_width$  array now holds  $\gamma + \beta(cur\_p) - \alpha(a)$ ; so  $\delta$  can be obtained by subtracting  $cur\_active\_width$  from the quantity  $\gamma + \beta(cur\_p) - \alpha(cur\_p)$ . The latter quantity can be regarded as the length of a line “from  $cur\_p$  to  $cur\_p$ ”; we call it the  $break\_width$  at  $cur\_p$ .

The  $break\_width$  is usually negative, since it consists of the background (which is normally zero) minus the width of nodes following  $cur\_p$  that are eliminated after a break. If, for example, node  $cur\_p$  is a glue node, the width of this glue is subtracted from the background; and we also look ahead to eliminate all subsequent glue and penalty and kern and math nodes, subtracting their widths as well.

Kern nodes do not disappear at a line break unless they are *explicit*.

**define**  $set\_break\_width\_to\_background(\#) \equiv break\_width[\#] \leftarrow background[\#]$

⟨ Compute the values of  $break\_width$  848 ⟩  $\equiv$

```

begin no_break_yet  $\leftarrow false$ ; do_all_six(set_break_width_to_background); s  $\leftarrow cur\_p$ ;
if break_type > unhyphenated then
  if cur_p  $\neq null$  then ⟨ Compute the discretionary  $break\_width$  values 851 ⟩;
while s  $\neq null$  do
  begin if is_char_node(s) then
    begin if chain then
      begin break_width[1]  $\leftarrow break\_width[1] - width(cur\_kanji\_skip)$ ;
      break_width[2 + stretch_order(cur_kanji_skip)]  $\leftarrow break\_width[2 + stretch\_order(cur\_kanji\_skip)] -$ 
        stretch(cur_kanji_skip); break_width[6]  $\leftarrow break\_width[6] - shrink(cur\_kanji\_skip)$ ;
      end;
      goto done
    end;
  case type(s) of
    glue_node: ⟨ Subtract glue from  $break\_width$  849 ⟩;
    penalty_node: do_nothing;
    math_node: break_width[1]  $\leftarrow break\_width[1] - width(s)$ ;
    kern_node: if (subtype(s)  $\neq explicit$ )  $\wedge$  (subtype(s)  $\neq ita\_kern$ ) then goto done
      else break_width[1]  $\leftarrow break\_width[1] - width(s)$ ;
  othercases goto done
  endcases;
  s  $\leftarrow link(s)$ ;
  end;
done: end

```

This code is used in section 847.

**849.** ⟨ Subtract glue from  $break\_width$  849 ⟩  $\equiv$

```

begin v  $\leftarrow glue\_ptr(s)$ ; break_width[1]  $\leftarrow break\_width[1] - width(v)$ ;
break_width[2 + stretch_order(v)]  $\leftarrow break\_width[2 + stretch\_order(v)] - stretch(v)$ ;
break_width[6]  $\leftarrow break\_width[6] - shrink(v)$ ;
end

```

This code is used in section 848.

**850.** When *cur\_p* is a discretionary break, the length of a line “from *cur\_p* to *cur\_p*” has to be defined properly so that the other calculations work out. Suppose that the pre-break text at *cur\_p* has length  $l_0$ , the post-break text has length  $l_1$ , and the replacement text has length  $l$ . Suppose also that  $q$  is the node following the replacement text. Then length of a line from *cur\_p* to  $q$  will be computed as  $\gamma + \beta(q) - \alpha(\textit{cur\_p})$ , where  $\beta(q) = \beta(\textit{cur\_p}) - l_0 + l$ . The actual length will be the background plus  $l_1$ , so the length from *cur\_p* to *cur\_p* should be  $\gamma + l_0 + l_1 - l$ . If the post-break text of the discretionary is empty, a break may also discard  $q$ ; in that unusual case we subtract the length of  $q$  and any other nodes that will be discarded after the discretionary break.

The value of  $l_0$  need not be computed, since *line\_break* will put it into the global variable *disc\_width* before calling *try\_break*.

```
⟨Global variables 13⟩ +=
disc_width: scaled; { the length of discretionary material preceding a break }
```

```
851. ⟨Compute the discretionary break_width values 851⟩ ≡
begin t ← replace_count(cur_p); v ← cur_p; s ← post_break(cur_p);
while t > 0 do
  begin decr(t); v ← link(v); ⟨Subtract the width of node v from break_width 852⟩;
  end;
while s ≠ null do
  begin ⟨Add the width of node s to break_width 853⟩;
  s ← link(s);
  end;
break_width[1] ← break_width[1] + disc_width;
if post_break(cur_p) = null then s ← link(v); { nodes may be discardable after the break }
end
```

This code is used in section 848.

**852.** Replacement texts and discretionary texts are supposed to contain only character nodes, kern nodes, ligature nodes, and box or rule nodes.

```
⟨Subtract the width of node v from break_width 852⟩ ≡
if is_char_node(v) then
  begin f ← font(v); break_width[1] ← break_width[1] - char_width(f)(orig_char_info(f)(character(v)));
  if font_dir[f] ≠ dir_default then v ← link(v);
  end
else case type(v) of
  ligature_node: begin f ← font(lig_char(v));
  break_width[1] ← break_width[1] - char_width(f)(orig_char_info(f)(character(lig_char(v))));
  end;
  hlist_node, vlist_node, dir_node, rule_node, kern_node: break_width[1] ← break_width[1] - width(v);
  disp_node: do_nothing;
  othercases confusion("disc1")
endcases
```

This code is used in section 851.

**853.**  $\langle$  Add the width of node  $s$  to  $break\_width$  853  $\equiv$

```

if  $is\_char\_node(s)$  then
  begin  $f \leftarrow font(s)$ ;  $break\_width[1] \leftarrow break\_width[1] + char\_width(f)(orig\_char\_info(f)(character(s)))$ ;
  if  $font\_dir[f] \neq dir\_default$  then  $s \leftarrow link(s)$ ;
  end
else case  $type(s)$  of
   $ligature\_node$ : begin  $f \leftarrow font(lig\_char(s))$ ;
     $break\_width[1] \leftarrow break\_width[1] + char\_width(f)(orig\_char\_info(f)(character(lig\_char(s))))$ ;
    end;
   $hlist\_node, vlist\_node, dir\_node, rule\_node, kern\_node$ :  $break\_width[1] \leftarrow break\_width[1] + width(s)$ ;
   $disp\_node$ :  $do\_nothing$ ;
  othercases  $confusion("disc2")$ 
endcases

```

This code is used in section 851.

**854.** We use the fact that  $type(active) \neq delta\_node$ .

```

define  $convert\_to\_break\_width(\#) \equiv mem[prev\_r + \#].sc \leftarrow$ 
   $mem[prev\_r + \#].sc - cur\_active\_width[\#] + break\_width[\#]$

  else print_int(serial(prev_break(passive)));
  end

```

This code is used in section 856.

**858.** The length of lines depends on whether the user has specified `\parshape` or `\hangindent`. If *par\_shape\_ptr* is not null, it points to a  $(2n + 1)$ -word record in *mem*, where the *info* in the first word contains the value of  $n$ , and the other  $2n$  words contain the left margins and line lengths for the first  $n$  lines of the paragraph; the specifications for line  $n$  apply to all subsequent lines. If *par\_shape\_ptr* = *null*, the shape of the paragraph depends on the value of  $n = \textit{hang\_after}$ ; if  $n \geq 0$ , hanging indentation takes place on lines  $n + 1, n + 2, \dots$ , otherwise it takes place on lines  $1, \dots, |n|$ . When hanging indentation is active, the left margin is *hang\_indent*, if *hang\_indent*  $\geq 0$ , else it is 0; the line length is *hsize* -  $|hang\_indent|$ . The normal setting is *par\_shape\_ptr* = *null*, *hang\_after* = 1, and *hang\_indent* = 0. Note that if *hang\_indent* = 0, the value of *hang\_after* is irrelevant.

```

⟨Global variables 13⟩ +=≡
easy_line: halfword; {line numbers > easy_line are equivalent in break nodes}
last_special_line: halfword; {line numbers > last_special_line all have the same width}

    else ⟨Set line length parameters in preparation for hanging indentation 860⟩
  else begin last_special_line ← info(par_shape_ptr) - 1;
    second_width ← mem[par_shape_ptr + 2 * (last_special_line + 1)].sc;
    second_indent ← mem[par_shape_ptr + 2 * last_special_line + 1].sc;
    end;
  if looseness = 0 then easy_line ← last_special_line
  else easy_line ← max_halfword

```

**860.** ⟨Set line length parameters in preparation for hanging indentation 860⟩ ≡

```

  begin last_special_line ← abs(hang_after);
  if hang_after < 0 then
    begin first_width ← hsize - abs(hang_indent);
    if hang_indent ≥ 0 then first_indent ← hang_indent
    else first_indent ← 0;
    second_width ← hsize; second_indent ← 0;
    end
  else begin first_width ← hsize; first_indent ← 0; second_width ← hsize - abs(hang_indent);
    if hang_indent ≥ 0 then second_indent ← hang_indent
    else second_indent ← 0;
    end;
  end

```

This code is used in section 859.

**861.** When we come to the following code, we have just encountered the first active node *r* whose *line\_number* field contains *l*. Thus we want to compute the length of the *l*th line of the current paragraph. Furthermore, we want to set *old\_l* to the last number in the class of line numbers equivalent to *l*.

```

⟨Compute the new line width 861⟩ ≡
  if l > easy_line then
    begin line_width ← second_width; old_l ← max_halfword - 1;
    end
  else begin old_l ← l;
    if l > last_special_line then line_width ← second_width
    else if par_shape_ptr = null then line_width ← first_width
    else line_width ← mem[par_shape_ptr + 2 * l].sc;
    end

```

This code is used in section 846.

**862.** The remaining part of *try\_break* deals with the calculation of demerits for a break from *r* to *cur\_p*.

The first thing to do is calculate the badness, *b*. This value will always be between zero and *inf\_bad* + 1; the latter value occurs only in the case of lines from *r* to *cur\_p* that cannot shrink enough to fit the necessary width. In such cases, node *r* will be deactivated. We also deactivate node *r* when a break at *cur\_p* is forced, since future breaks must go through a forced break.

```

⟨ Consider the demerits for a line from r to cur_p; deactivate node r if it should no longer be active; then
  goto continue if a line from r to cur_p is infeasible, otherwise record a new feasible break 862 ⟩ ≡
  begin artificial_demerits ← false;
  shortfall ← line_width − cur_active_width[1]; { we're this much too short }
  if shortfall > 0 then
    ⟨ Set the value of b to the badness for stretching the line, and compute the corresponding fit_class 863 ⟩
  else ⟨ Set the value of b to the badness for shrinking the line, and compute the corresponding fit_class 864 ⟩;
  if (b > inf_bad) ∨ (pi = eject_penalty) then ⟨ Prepare to deactivate node r, and goto deactivate unless
    there is a reason to consider lines of text from r to cur_p 865 ⟩
  else begin prev_r ← r;
    if b > threshold then goto continue;
    node_r_stays_active ← true;
  end;
  ⟨ Record a new feasible break 866 ⟩;
  if node_r_stays_active then goto continue; { prev_r has been set to r }
deactivate: ⟨ Deactivate node r 871 ⟩;
end

```

This code is used in section 840.

**863.** When a line must stretch, the available stretchability can be found in the subarray *cur\_active\_width*[2 . . 5], in units of points, fil, fill, and filll.

The present section is part of T<sub>E</sub>X's inner loop, and it is most often performed when the badness is infinite; therefore it is worth while to make a quick test for large width excess and small stretchability, before calling the *badness* subroutine.

```

⟨ Set the value of b to the badness for stretching the line, and compute the corresponding fit_class 863 ⟩ ≡
  if (cur_active_width[3] ≠ 0) ∨ (cur_active_width[4] ≠ 0) ∨ (cur_active_width[5] ≠ 0) then
    begin b ← 0; fit_class ← decent_fit; { infinite stretch }
  end
  else begin if shortfall > 7230584 then
    if cur_active_width[2] < 1663497 then
      begin b ← inf_bad; fit_class ← very_loose_fit; goto done1;
    end;
    b ← badness(shortfall, cur_active_width[2]);
    if b > 12 then
      if b > 99 then fit_class ← very_loose_fit
      else fit_class ← loose_fit
    else fit_class ← decent_fit;
  done1: end

```

This code is used in section 862.

**864.** Shrinkability is never infinite in a paragraph; we can shrink the line from  $r$  to  $cur\_p$  by at most  $cur\_active\_width[6]$ .

```

⟨Set the value of  $b$  to the badness for shrinking the line, and compute the corresponding  $fit\_class$  864⟩ ≡
  begin if  $-shortfall > cur\_active\_width[6]$  then  $b \leftarrow inf\_bad + 1$ 
  else  $b \leftarrow badness(-shortfall, cur\_active\_width[6])$ ;
  if  $b > 12$  then  $fit\_class \leftarrow tight\_fit$  else  $fit\_class \leftarrow decent\_fit$ ;
  end

```

This code is used in section 862.

**865.** During the final pass, we dare not lose all active nodes, lest we lose touch with the line breaks already found. The code shown here makes sure that such a catastrophe does not happen, by permitting overfull boxes as a last resort. This particular part of T<sub>E</sub>X was a source of several subtle bugs before the correct program logic was finally discovered; readers who seek to “improve” T<sub>E</sub>X should therefore think thrice before daring to make any changes here.

```

⟨Prepare to deactivate node  $r$ , and goto deactivate unless there is a reason to consider lines of text from  $r$  to  $cur\_p$  865⟩ ≡
  begin if  $final\_pass \wedge (minimum\_demerits = awful\_bad) \wedge (link(r) = last\_active) \wedge (prev\_r = active)$  then
     $artificial\_demerits \leftarrow true$  { set demerits zero, this break is forced }
  else if  $b > threshold$  then goto deactivate;
   $node\_r\_stays\_active \leftarrow false$ ;
  end

```

This code is used in section 862.

**866.** When we get to this part of the code, the line from  $r$  to  $cur\_p$  is feasible, its badness is  $b$ , and its fitness classification is  $fit\_class$ . We don’t want to make an active node for this break yet, but we will compute the total demerits and record them in the  $minimal\_demerits$  array, if such a break is the current champion among all ways to get to  $cur\_p$  in a given line-number class and fitness class.

```

⟨Record a new feasible break 866⟩ ≡
  if  $artificial\_demerits$  then  $d \leftarrow 0$ 
  else ⟨Compute the demerits,  $d$ , from  $r$  to  $cur\_p$  870⟩;
  stat if  $tracing\_paragraphs > 0$  then ⟨Print a symbolic description of this feasible break 867⟩;
  tats
   $d \leftarrow d + total\_demerits(r)$ ; { this is the minimum total demerits from the beginning to  $cur\_p$  via  $r$  }
  if  $d \leq minimal\_demerits[fit\_class]$  then
    begin  $minimal\_demerits[fit\_class] \leftarrow d$ ;  $best\_place[fit\_class] \leftarrow break\_node(r)$ ;  $best\_pl\_line[fit\_class] \leftarrow l$ ;
    if  $d < minimum\_demerits$  then  $minimum\_demerits \leftarrow d$ ;
    end

```

This code is used in section 862.

**867.**  $\langle$  Print a symbolic description of this feasible break 867  $\rangle \equiv$

```

begin if printed_node  $\neq$  cur_p then
   $\langle$  Print the list between printed_node and cur_p, then set printed_node  $\leftarrow$  cur_p 868  $\rangle$ ;
  print_nl("@");
  if cur_p = null then print_esc("par")
  else if (type(cur_p)  $\neq$  glue_node)  $\wedge$  ( $\neg$ is_char_node(cur_p)) then
    begin if type(cur_p) = penalty_node then print_esc("penalty")
    else if type(cur_p) = disc_node then print_esc("discretionary")
    else if type(cur_p) = kern_node then print_esc("kern")
    else print_esc("math");
    end;
  print("_via_@@");
  if break_node(r) = null then print_char("0")
  else print_int(serial(break_node(r)));
  print("_b=");
  if b > inf_bad then print_char("*") else print_int(b);
  print("_p="); print_int(pi); print("_d=");
  if artificial_demerits then print_char("*") else print_int(d);
  end

```

This code is used in section 866.

**868.**  $\langle$  Print the list between *printed\_node* and *cur\_p*, then set *printed\_node*  $\leftarrow$  *cur\_p* 868  $\rangle \equiv$

```

begin print_nl("");
  if cur_p = null then short_display(link(printed_node))
  else begin save_link  $\leftarrow$  link(cur_p); link(cur_p)  $\leftarrow$  null; print_nl("");
    short_display(link(printed_node)); link(cur_p)  $\leftarrow$  save_link;
  end;
  printed_node  $\leftarrow$  cur_p;
end

```

This code is used in section 867.

**869.** When the data for a discretionary break is being displayed, we will have printed the *pre\_break* and *post\_break* lists; we want to skip over the third list, so that the discretionary data will not appear twice. The following code is performed at the very end of *try\_break*.

$\langle$  Update the value of *printed\_node* for symbolic displays 869  $\rangle \equiv$

```

if cur_p = printed_node then
  if cur_p  $\neq$  null then
    if type(cur_p) = disc_node then
      begin t  $\leftarrow$  replace_count(cur_p);
      while t > 0 do
        begin decr(t); printed_node  $\leftarrow$  link(printed_node);
        end;
      end
    end

```

This code is used in section 840.

```

870.  ⟨ Compute the demerits,  $d$ , from  $r$  to  $cur\_p$  870 ⟩ ≡
  begin  $d \leftarrow line\_penalty + b$ ;
  if  $abs(d) \geq 10000$  then  $d \leftarrow 100000000$  else  $d \leftarrow d * d$ ;
  if  $pi \neq 0$  then
    if  $pi > 0$  then  $d \leftarrow d + pi * pi$ 
    else if  $pi > eject\_penalty$  then  $d \leftarrow d - pi * pi$ ;
  if  $(break\_type = hyphenated) \wedge (type(r) = hyphenated)$  then
    if  $cur\_p \neq null$  then  $d \leftarrow d + double\_hyphen\_demerits$ 
    else  $d \leftarrow d + final\_hyphen\_demerits$ ;
  if  $abs(intcast(fit\_class) - intcast(fitness(r))) > 1$  then  $d \leftarrow d + adj\_demerits$ ;
  end

```

This code is used in section 866.

**871.** When an active node disappears, we must delete an adjacent delta node if the active node was at the beginning or the end of the active list, or if it was surrounded by delta nodes. We also must preserve the property that  $cur\_active\_width$  represents the length of material from  $link(prev\_r)$  to  $cur\_p$ .

```

  define  $combine\_two\_deltas(\#) \equiv mem[prev\_r + \#].sc \leftarrow mem[prev\_r + \#].sc + mem[r + \#].sc$ 
  define  $downdate\_width(\#) \equiv cur\_active\_width[\#] \leftarrow cur\_active\_width[\#] - mem[prev\_r + \#].sc$ 
  ⟨ Deactivate node  $r$  871 ⟩ ≡
   $link(prev\_r) \leftarrow link(r)$ ;  $free\_node(r, active\_node\_size)$ ;
  if  $prev\_r = active$  then ⟨ Update the active widths, since the first active node has been deleted 872 ⟩
  else if  $type(prev\_r) = delta\_node$  then
    begin  $r \leftarrow link(prev\_r)$ ;
    if  $r = last\_active$  then
      begin  $do\_all\_six(downdate\_width)$ ;  $link(prev\_prev\_r) \leftarrow last\_active$ ;
       $free\_node(prev\_r, delta\_node\_size)$ ;  $prev\_r \leftarrow prev\_prev\_r$ ;
      end
    else if  $type(r) = delta\_node$  then
      begin  $do\_all\_six(update\_width)$ ;  $do\_all\_six(combine\_two\_deltas)$ ;  $link(prev\_r) \leftarrow link(r)$ ;
       $free\_node(r, delta\_node\_size)$ ;
      end;
    end

```

This code is used in section 862.

**872.** The following code uses the fact that  $type(last\_active) \neq delta\_node$ . If the active list has just become empty, we do not need to update the  $active\_width$  array, since it will be initialized when an active node is next inserted.

```

  define  $update\_active(\#) \equiv active\_width[\#] \leftarrow active\_width[\#] + mem[r + \#].sc$ 
  ⟨ Update the active widths, since the first active node has been deleted 872 ⟩ ≡
  begin  $r \leftarrow link(active)$ ;
  if  $type(r) = delta\_node$  then
    begin  $do\_all\_six(update\_active)$ ;  $do\_all\_six(copy\_to\_cur\_active)$ ;  $link(active) \leftarrow link(r)$ ;
     $free\_node(r, delta\_node\_size)$ ;
    end;
  end

```

This code is used in section 871.

**873. Breaking paragraphs into lines, continued.** So far we have gotten a little way into the *line\_break* routine, having covered its important *try\_break* subroutine. Now let's consider the rest of the process.

The main loop of *line\_break* traverses the given hlist, starting at *link(temp\_head)*, and calls *try\_break* at each legal breakpoint. A variable called *auto\_breaking* is set to true except within math formulas, since glue nodes are not legal breakpoints when they appear in formulas.

The current node of interest in the hlist is pointed to by *cur\_p*. Another variable, *prev\_p*, is usually one step behind *cur\_p*, but the real meaning of *prev\_p* is this: If *type(cur\_p) = glue\_node* then *cur\_p* is a legal breakpoint if and only if *auto\_breaking* is true and *prev\_p* does not point to a glue node, penalty node, explicit kern node, or math node.

The following declarations provide for a few other local variables that are used in special calculations.

```

⟨Local variables for line breaking 873⟩ ≡
auto_breaking: boolean; { is node cur_p outside a formula? }
prev_p: pointer; { helps to determine when glue nodes are breakpoints }
q, r, s, prev_s: pointer; { miscellaneous nodes of temporary interest }
f, post_f: internal_font_number; { used when calculating character widths }
post_p: pointer;
cc: ASCII_code;
first_use: boolean;

```

See also section 904.

This code is used in section 826.

**874.** The ‘loop’ in the following code is performed at most thrice per call of *line\_break*, since it is actually a pass over the entire paragraph.

```

⟨Find optimal breakpoints 874⟩ ≡
  threshold ← pretolerance;
  if threshold ≥ 0 then
    begin stat if tracing_paragraphs > 0 then
      begin begin_diagnostic; print_nl("@firstpass"); end; tats
      second_pass ← false; final_pass ← false;
    end
  else begin threshold ← tolerance; second_pass ← true; final_pass ← (emergency_stretch ≤ 0);
    stat if tracing_paragraphs > 0 then begin_diagnostic;
    tats
  end;
  loop begin if threshold > inf_bad then threshold ← inf_bad;
    if second_pass then ⟨Initialize for hyphenating a paragraph 902⟩;
    ⟨Create an active breakpoint representing the beginning of the paragraph 875⟩;
    cur_p ← link(temp_head); auto_breaking ← true;
    prev_p ← cur_p; { glue at beginning is not a legal breakpoint }
    while (cur_p ≠ null) ∧ (link(active) ≠ last_active) do ⟨Call try_break if cur_p is a legal breakpoint;
      on the second pass, also try to hyphenate the next word, if cur_p is a glue node; then advance
      cur_p to the next node of the paragraph that could possibly be a legal breakpoint 877⟩;
    if cur_p = null then ⟨Try the final line break at the end of the paragraph, and goto done if the
      desired breakpoints have been found 884⟩;
    ⟨Clean up the memory by removing the break nodes 876⟩;
    if ¬second_pass then
      begin stat if tracing_paragraphs > 0 then print_nl("@secondpass"); tats
      threshold ← tolerance; second_pass ← true; final_pass ← (emergency_stretch ≤ 0);
      end { if at first you don't succeed, ... }
    else begin stat if tracing_paragraphs > 0 then print_nl("@emergencypass"); tats
      background[2] ← background[2] + emergency_stretch; final_pass ← true;
    end;
  end;
done: stat if tracing_paragraphs > 0 then
  begin end_diagnostic(true); normalize_selector;
  end;
  tats

```

This code is used in section 826.

**875.** The active node that represents the starting point does not need a corresponding passive node.

```

define store_background(#) ≡ active_width[#] ← background[#]
⟨Create an active breakpoint representing the beginning of the paragraph 875⟩ ≡
  q ← get_node(active_node_size); type(q) ← unhyphenated; fitness(q) ← decent_fit; link(q) ← last_active;
  break_node(q) ← null; line_number(q) ← prev_graf + 1; total_demerits(q) ← 0; link(active) ← q;
  do_all_six(store_background);
  passive ← null; printed_node ← temp_head; pass_number ← 0; font_in_short_display ← null_font

```

This code is used in section 874.

**876.**  $\langle$  Clean up the memory by removing the break nodes 876  $\rangle \equiv$

```

q ← link(active);
while q ≠ last_active do
  begin cur_p ← link(q);
  if type(q) = delta_node then free_node(q, delta_node_size)
  else free_node(q, active_node_size);
  q ← cur_p;
  end;
q ← passive;
while q ≠ null do
  begin cur_p ← link(q); free_node(q, passive_node_size); q ← cur_p;
  end

```

This code is used in sections 826 and 874.

**877.** Here is the main switch in the *line\_break* routine, where legal breaks are determined. As we move through the hlist, we need to keep the *active\_width* array up to date, so that the badness of individual lines is readily calculated by *try\_break*. It is convenient to use the short name *act\_width* for the component of active width that represents real width as opposed to glue.

```

define act_width ≡ active_width[1] { length from first active node to current node }
define kern_break ≡
  begin if ¬is_char_node(link(cur_p)) ∧ auto_breaking then
    if type(link(cur_p)) = glue_node then try_break(0, unhyphenated);
    act_width ← act_width + width(cur_p);
  end

```

$\langle$  Call *try\_break* if *cur\_p* is a legal breakpoint; on the second pass, also try to hyphenate the next word, if *cur\_p* is a glue node; then advance *cur\_p* to the next node of the paragraph that could possibly be a legal breakpoint 877  $\rangle \equiv$

```

begin if is_char_node(cur_p) then
   $\langle$  Advance cur_p to the node following the present string of characters 878  $\rangle$ ;
case type(cur_p) of
  hlist_node, vlist_node, dir_node, rule_node: act_width ← act_width + width(cur_p);
  whatsit_node:  $\langle$  Advance past a whatsit node in the line_break loop 1375  $\rangle$ ;
  glue_node: begin  $\langle$  If node cur_p is a legal breakpoint, call try_break; then update the active widths by
    including the glue in glue_ptr(cur_p) 879  $\rangle$ ;
    if second_pass ∧ auto_breaking then  $\langle$  Try to hyphenate the following word 905  $\rangle$ ;
    end;
  kern_node: if (subtype(cur_p) = explicit) ∨ (subtype(cur_p) = ita_kern) then kern_break
    else act_width ← act_width + width(cur_p);
  ligature_node: begin f ← font(lig_char(cur_p));
    act_width ← act_width + char_width(f)(char_info(f)(character(lig_char(cur_p))));
    end;
  disc_node:  $\langle$  Try to break after a discretionary fragment, then goto done5 880  $\rangle$ ;
  math_node: begin auto_breaking ← (subtype(cur_p) = after); kern_break;
  end;
  penalty_node: try_break(penalty(cur_p), unhyphenated);
  disp_node, mark_node, ins_node, adjust_node: do_nothing;
othercases confusion("paragraph")
endcases;
prev_p ← cur_p; cur_p ← link(cur_p);
done5: end

```

This code is used in section 874.

**878.** The code that passes over the characters of words in a paragraph is part of TEX's inner loop, so it has been streamlined for speed. We use the fact that '\parfillskip' glue appears at the end of each paragraph; it is therefore unnecessary to check if  $link(cur\_p) = null$  when  $cur\_p$  is a character node.

⟨Advance  $cur\_p$  to the node following the present string of characters 878⟩ ≡

```

begin chain ← false;
if is_char_node(cur_p) then
  if font_dir[font(cur_p)] ≠ dir_default then
    begin case type(prev_p) of
      hlist_node, vlist_node, dir_node, rule_node, ligature_node, disc_node, math_node: begin cur_p ← prev_p;
        try_break(0, unhyphenated); cur_p ← link(cur_p);
      end;
    othercases do_nothing;
    endcases;
  end;
prev_p ← cur_p; post_p ← cur_p; post_f ← font(post_p);
repeat f ← post_f; cc ← character(cur_p);
  act_width ← act_width + char_width(f)(orig_char_info(f)(cc)); post_p ← link(cur_p);
  if font_dir[f] ≠ dir_default then
    begin prev_p ← cur_p; cur_p ← post_p; post_p ← link(post_p);
    if is_char_node(post_p) then
      begin post_f ← font(post_p);
      if font_dir[post_f] ≠ dir_default then chain ← true
      else chain ← false;
      try_break(0, unhyphenated);
    end
  else begin chain ← false;
    case type(post_p) of
      hlist_node, vlist_node, dir_node, rule_node, ligature_node, disc_node, math_node:
        try_break(0, unhyphenated);
    othercases do_nothing;
    endcases;
  end;
  if chain then
    begin if first_use then
      begin check_shrinkage(cur_kanji_skip); first_use ← false;
      end;
      act_width ← act_width + width(cur_kanji_skip); active_width[2 + stretch_order(cur_kanji_skip)] ←
        active_width[2 + stretch_order(cur_kanji_skip)] + stretch(cur_kanji_skip);
      active_width[6] ← active_width[6] + shrink(cur_kanji_skip);
    end;
    prev_p ← cur_p;
  end
  else if is_char_node(post_p) then
    begin post_f ← font(post_p); chain ← false;
    if font_dir[post_f] ≠ dir_default then try_break(0, unhyphenated);
    end;
    cur_p ← post_p;
  until ¬is_char_node(cur_p);
  chain ← false;
end

```

This code is used in section 877.

**879.** When node *cur\_p* is a glue node, we look at *prev\_p* to see whether or not a breakpoint is legal at *cur\_p*, as explained above.

```

⟨If node cur_p is a legal breakpoint, call try_break; then update the active widths by including the glue in
  glue_ptr(cur_p) 879⟩ ≡
if auto_breaking then
  begin if is_char_node(prev_p) then try_break(0, unhyphenated)
  else if precedes_break(prev_p) then try_break(0, unhyphenated)
  else if type(prev_p) = kern_node then
    if (subtype(prev_p) ≠ explicit) ∧ (subtype(prev_p) ≠ ita_kern) then try_break(0, unhyphenated);
  end;
check_shrinkage(glue_ptr(cur_p)); q ← glue_ptr(cur_p); act_width ← act_width + width(q);
active_width[2 + stretch_order(q)] ← active_width[2 + stretch_order(q)] + stretch(q);
active_width[6] ← active_width[6] + shrink(q)

```

This code is used in section 877.

**880.** The following code knows that discretionary texts contain only character nodes, kern nodes, box nodes, rule nodes, and ligature nodes.

```

⟨Try to break after a discretionary fragment, then goto done5 880⟩ ≡
begin s ← pre_break(cur_p); disc_width ← 0;
if s = null then try_break(ex_hyphen_penalty, hyphenated)
else begin repeat ⟨Add the width of node s to disc_width 881⟩;
  s ← link(s);
  until s = null;
  act_width ← act_width + disc_width; try_break(hyphen_penalty, hyphenated);
  act_width ← act_width - disc_width;
end;
r ← replace_count(cur_p); s ← link(cur_p);
while r > 0 do
  begin ⟨Add the width of node s to act_width 882⟩;
  decr(r); s ← link(s);
  end;
prev_p ← cur_p; cur_p ← s; goto done5;
end

```

This code is used in section 877.

```

881. ⟨Add the width of node s to disc_width 881⟩ ≡
if is_char_node(s) then
  begin f ← font(s); disc_width ← disc_width + char_width(f)(orig_char_info(f)(character(s)));
  if font_dir[f] ≠ dir_default then s ← link(s)
  end
else case type(s) of
  ligature_node: begin f ← font(lig_char(s));
  disc_width ← disc_width + char_width(f)(orig_char_info(f)(character(lig_char(s))));
  end;
  hlist_node, vlist_node, dir_node, rule_node, kern_node: disc_width ← disc_width + width(s);
  disp_node: do_nothing;
  othercases confusion("disc3")
endcases

```

This code is used in section 880.

```

882.  ⟨ Add the width of node s to act_width 882 ⟩ ≡
  if is_char_node(s) then
    begin f ← font(s); act_width ← act_width + char_width(f)(orig_char_info(f)(character(s)));
    if font_dir[f] ≠ dir_default then s ← link(s)
    end
  else case type(s) of
    ligature_node: begin f ← font(lig_char(s));
      act_width ← act_width + char_width(f)(orig_char_info(f)(character(lig_char(s))));
    end;
    hlist_node, vlist_node, dir_node, rule_node, kern_node: act_width ← act_width + width(s);
    disp_node: do_nothing;
    othercases confusion("disc4")
  endcases

```

This code is used in section 880.

**883.** The forced line break at the paragraph’s end will reduce the list of breakpoints so that all active nodes represent breaks at *cur\_p* = *null*. On the first pass, we insist on finding an active node that has the correct “looseness.” On the final pass, there will be at least one active node, and we will match the desired looseness as well as we can.

The global variable *best\_bet* will be set to the active node for the best way to break the paragraph, and a few other variables are used to help determine what is best.

```

⟨ Global variables 13 ⟩ +≡
best_bet: pointer; { use this passive node and its predecessors }
fewest_demerits: integer; { the demerits associated with best_bet }
best_line: halfword; { line number following the last line of the new paragraph }
actual_looseness: integer; { the difference between line_number(best_bet) and the optimum best_line }
line_diff: integer; { the difference between the current line number and the optimum best_line }

```

**884.** ⟨ Try the final line break at the end of the paragraph, and **goto** *done* if the desired breakpoints have been found 884 ⟩ ≡

```

begin try_break(eject_penalty, hyphenated);
if link(active) ≠ last_active then
  begin ⟨ Find an active node with fewest demerits 885 ⟩;
  if looseness = 0 then goto done;
  ⟨ Find the best active node for the desired looseness 886 ⟩;
  if (actual_looseness = looseness) ∨ final_pass then goto done;
  end;
end

```

This code is used in section 874.

```

885.  ⟨ Find an active node with fewest demerits 885 ⟩ ≡
  r ← link(active); fewest_demerits ← awful_bad;
  repeat if type(r) ≠ delta_node then
    if total_demerits(r) < fewest_demerits then
      begin fewest_demerits ← total_demerits(r); best_bet ← r;
      end;
    r ← link(r);
  until r = last_active;
  best_line ← line_number(best_bet)

```

This code is used in section 884.

**886.** The adjustment for a desired looseness is a slightly more complicated version of the loop just considered. Note that if a paragraph is broken into segments by displayed equations, each segment will be subject to the looseness calculation, independently of the other segments.

```

⟨Find the best active node for the desired looseness 886⟩ ≡
  begin  $r \leftarrow \text{link}(\text{active}); \text{actual\_looseness} \leftarrow 0;$ 
  repeat if  $\text{type}(r) \neq \text{delta\_node}$  then
    begin  $\text{line\_diff} \leftarrow \text{intcast}(\text{line\_number}(r)) - \text{intcast}(\text{best\_line});$ 
    if  $((\text{line\_diff} < \text{actual\_looseness}) \wedge (\text{looseness} \leq \text{line\_diff})) \vee$ 
       $((\text{line\_diff} > \text{actual\_looseness}) \wedge (\text{looseness} \geq \text{line\_diff}))$  then
      begin  $\text{best\_bet} \leftarrow r; \text{actual\_looseness} \leftarrow \text{line\_diff}; \text{fewest\_demerits} \leftarrow \text{total\_demerits}(r);$ 
      end
    else if  $(\text{line\_diff} = \text{actual\_looseness}) \wedge (\text{total\_demerits}(r) < \text{fewest\_demerits})$  then
      begin  $\text{best\_bet} \leftarrow r; \text{fewest\_demerits} \leftarrow \text{total\_demerits}(r);$ 
      end;
    end;
   $r \leftarrow \text{link}(r);$ 
  until  $r = \text{last\_active};$ 
   $\text{best\_line} \leftarrow \text{line\_number}(\text{best\_bet});$ 
  end

```

This code is used in section 884.

**887.** Once the best sequence of breakpoints has been found (hurray), we call on the procedure *post\_line\_break* to finish the remainder of the work. (By introducing this subprocedure, we are able to keep *line\_break* from getting extremely long.)

```

⟨Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and
  append them to the current vertical list 887⟩ ≡
   $\text{post\_line\_break}(\text{final\_widow\_penalty})$ 

```

This code is used in section 826.

**888.** The total number of lines that will be set by *post\_line\_break* is  $best\_line - prev\_graf - 1$ . The last breakpoint is specified by  $break\_node(best\_bet)$ , and this passive node points to the other breakpoints via the *prev\_break* links. The finishing-up phase starts by linking the relevant passive nodes in forward order, changing *prev\_break* to *next\_break*. (The *next\_break* fields actually reside in the same memory space as the *prev\_break* fields did, but we give them a new name because of their new significance.) Then the lines are justified, one by one.

```

define next_break  $\equiv$  prev_break { new name for prev_break after links are reversed }
⟨ Declare subprocedures for line_break 837 ⟩ +≡
procedure post_line_break(final_widow_penalty : integer);
label done, done1;
var q, r, s: pointer; { temporary registers for list manipulation }
    disc_break: boolean; { was the current break at a discretionary node? }
    post_disc_break: boolean; { and did it have a nonempty post-break part? }
    cur_width: scaled; { width of line number cur_line }
    cur_indent: scaled; { left margin of line number cur_line }
    t: quarterword; { used for replacement counts in discretionary nodes }
    pen: integer; { use when calculating penalties between lines }
    cur_line: halfword; { the current line number being justified }
begin ⟨ Reverse the links of the relevant passive nodes, setting cur_p to the first breakpoint 889 ⟩;
cur_line  $\leftarrow$  prev_graf + 1; last_disp  $\leftarrow$  0;
repeat ⟨ Justify the line ending at breakpoint cur_p, and append it to the current vertical list, together
    with associated penalties and other insertions 891 ⟩;
    incr(cur_line); cur_p  $\leftarrow$  next_break(cur_p);
    if cur_p  $\neq$  null then
        if  $\neg$ post_disc_break then ⟨ Prune unwanted nodes at the beginning of the next line 890 ⟩;
    until cur_p = null;
if (cur_line  $\neq$  best_line)  $\vee$  (link(temp_head)  $\neq$  null) then confusion("line_breaking");
prev_graf  $\leftarrow$  best_line - 1;
end;

```

**889.** The job of reversing links in a list is conveniently regarded as the job of taking items off one stack and putting them on another. In this case we take them off a stack pointed to by *q* and having *prev\_break* fields; we put them on a stack pointed to by *cur\_p* and having *next\_break* fields. Node *r* is the passive node being moved from stack to stack.

```

⟨ Reverse the links of the relevant passive nodes, setting cur_p to the first breakpoint 889 ⟩  $\equiv$ 
q  $\leftarrow$  break_node(best_bet); cur_p  $\leftarrow$  null;
repeat r  $\leftarrow$  q; q  $\leftarrow$  prev_break(q); next_break(r)  $\leftarrow$  cur_p; cur_p  $\leftarrow$  r;
until q = null

```

This code is used in section 888.

**890.** Glue and penalty and kern and math nodes are deleted at the beginning of a line, except in the anomalous case that the node to be deleted is actually one of the chosen breakpoints. Otherwise the pruning done here is designed to match the lookahead computation in *try\_break*, where the *break\_width* values are computed for non-discretionary breakpoints.

```

⟨Prune unwanted nodes at the beginning of the next line 890⟩ ≡
  begin r ← temp_head;
  loop begin q ← link(r);
    if q = cur_break(cur_p) then goto done1; { cur_break(cur_p) is the next breakpoint }
    { now q cannot be null }
    if is_char_node(q) then goto done1;
    if non_discardable(q) then goto done1;
    if type(q) = kern_node then
      if (subtype(q) ≠ explicit) ∧ (subtype(q) ≠ ita_kern) then goto done1;
    r ← q; { now type(q) = glue_node, kern_node, math_node or penalty_node }
  end;
done1: if r ≠ temp_head then
  begin link(r) ← null; flush_node_list(link(temp_head)); link(temp_head) ← q;
  end;
end

```

This code is used in section 888.

**891.** The current line to be justified appears in a horizontal list starting at *link(temp\_head)* and ending at *cur\_break(cur\_p)*. If *cur\_break(cur\_p)* is a glue node, we reset the glue to equal the *right\_skip* glue; otherwise we append the *right\_skip* glue at the right. If *cur\_break(cur\_p)* is a discretionary node, we modify the list so that the discretionary break is compulsory, and we set *disc\_break* to *true*. We also append the *left\_skip* glue at the left of the line, unless it is zero.

```

⟨Justify the line ending at breakpoint cur_p, and append it to the current vertical list, together with
associated penalties and other insertions 891⟩ ≡
  ⟨Modify the end of the line to reflect the nature of the break and to include \rightskip; also set the
proper value of disc_break 892⟩;
  ⟨Put the \leftskip glue at the left and detach this line 898⟩;
  ⟨Call the packaging subroutine, setting just_box to the justified box 900⟩;
  ⟨Append the new box to the current vertical list, followed by the list of special nodes taken out of the
box by the packager 899⟩;
  ⟨Append a penalty node, if a nonzero penalty is appropriate 901⟩

```

This code is used in section 888.

**892.** At the end of the following code,  $q$  will point to the final node on the list about to be justified.  
 ⟨Modify the end of the line to reflect the nature of the break and to include `\rightskip`; also set the proper value of `disc.break` 892⟩ ≡

```

 $q \leftarrow cur\_break(cur\_p)$ ;  $disc\_break \leftarrow false$ ;  $post\_disc\_break \leftarrow false$ ;
if  $q \neq null$  then {  $q$  may be a char_node }
  begin if  $\neg is\_char\_node(q)$  then
    if  $type(q) = glue\_node$  then
      begin  $delete\_glue\_ref(glue\_ptr(q))$ ;  $glue\_ptr(q) \leftarrow right\_skip$ ;  $subtype(q) \leftarrow right\_skip\_code + 1$ ;
       $add\_glue\_ref(right\_skip)$ ; goto done;
    end
    else begin if  $type(q) = disc\_node$  then
      ⟨Change discretionary to compulsory and set  $disc\_break \leftarrow true$  893⟩
    else if  $(type(q) = math\_node) \vee (type(q) = kern\_node)$  then  $width(q) \leftarrow 0$ ;
    end
  end
else begin  $q \leftarrow temp\_head$ ;
  while  $link(q) \neq null$  do  $q \leftarrow link(q)$ ;
end;
  ⟨Put the \rightskip glue after node  $q$  897⟩;
done:
```

This code is used in section 891.

**893.** ⟨Change discretionary to compulsory and set  $disc\_break \leftarrow true$  893⟩ ≡

```

begin  $t \leftarrow replace\_count(q)$ ;
  ⟨Destroy the  $t$  nodes following  $q$ , and make  $r$  point to the following node 894⟩;
if  $post\_break(q) \neq null$  then ⟨Transplant the post-break list 895⟩;
if  $pre\_break(q) \neq null$  then ⟨Transplant the pre-break list 896⟩;
   $link(q) \leftarrow r$ ;  $disc\_break \leftarrow true$ ;
end
```

This code is used in section 892.

**894.** ⟨Destroy the  $t$  nodes following  $q$ , and make  $r$  point to the following node 894⟩ ≡

```

if  $t = 0$  then  $r \leftarrow link(q)$ 
else begin  $r \leftarrow q$ ;
  while  $t > 1$  do
    begin  $r \leftarrow link(r)$ ;  $decr(t)$ ;
    end;
   $s \leftarrow link(r)$ ;  $r \leftarrow link(s)$ ;  $link(s) \leftarrow null$ ;  $flush\_node\_list(link(q))$ ;  $replace\_count(q) \leftarrow 0$ ;
end
```

This code is used in section 893.

**895.** We move the post-break list from inside node  $q$  to the main list by reattaching it just before the present node  $r$ , then resetting  $r$ .

⟨Transplant the post-break list 895⟩ ≡

```

begin  $s \leftarrow post\_break(q)$ ;
while  $link(s) \neq null$  do  $s \leftarrow link(s)$ ;
   $link(s) \leftarrow r$ ;  $r \leftarrow post\_break(q)$ ;  $post\_break(q) \leftarrow null$ ;  $post\_disc\_break \leftarrow true$ ;
end
```

This code is used in section 893.

**896.** We move the pre-break list from inside node  $q$  to the main list by reattaching it just after the present node  $q$ , then resetting  $q$ .

```
⟨Transplant the pre-break list 896⟩ ≡
  begin  $s \leftarrow pre\_break(q)$ ;  $link(q) \leftarrow s$ ;
  while  $link(s) \neq null$  do  $s \leftarrow link(s)$ ;
   $pre\_break(q) \leftarrow null$ ;  $q \leftarrow s$ ;
  end
```

This code is used in section 893.

**897.** ⟨Put the `\rightskip` glue after node  $q$  897⟩ ≡  
 $r \leftarrow new\_param\_glue(right\_skip\_code)$ ;  $link(r) \leftarrow link(q)$ ;  $link(q) \leftarrow r$ ;  $q \leftarrow r$

This code is used in section 892.

**898.** The following code begins with  $q$  at the end of the list to be justified. It ends with  $q$  at the beginning of that list, and with  $link(temp\_head)$  pointing to the remainder of the paragraph, if any.

```
⟨Put the \leftskip glue at the left and detach this line 898⟩ ≡
   $r \leftarrow link(q)$ ;  $link(q) \leftarrow null$ ;  $q \leftarrow link(temp\_head)$ ;  $link(temp\_head) \leftarrow r$ ;
  if  $last\_disp \neq 0$  then
    begin  $r \leftarrow get\_node(small\_node\_size)$ ;  $type(r) \leftarrow disp\_node$ ;  $disp\_dimen(r) \leftarrow last\_disp$ ;  $link(r) \leftarrow q$ ;
     $q \leftarrow r$ ;
    end;
  if  $left\_skip \neq zero\_glue$  then
    begin  $r \leftarrow new\_param\_glue(left\_skip\_code)$ ;  $link(r) \leftarrow q$ ;  $q \leftarrow r$ ;
    end
```

This code is used in section 891.

**899.** ⟨Append the new box to the current vertical list, followed by the list of special nodes taken out of the box by the packager 899⟩ ≡

```
 $append\_to\_vlist(just\_box)$ ;
if  $adjust\_head \neq adjust\_tail$  then
  begin  $link(tail) \leftarrow link(adjust\_head)$ ;  $tail \leftarrow adjust\_tail$ ;
  end;
 $adjust\_tail \leftarrow null$ 
```

This code is used in section 891.

**900.** Now  $q$  points to the hlist that represents the current line of the paragraph. We need to compute the appropriate line width, pack the line into a box of this size, and shift the box by the appropriate amount of indentation.

```
⟨Call the packaging subroutine, setting just_box to the justified box 900⟩ ≡
  if  $cur\_line > last\_special\_line$  then
    begin  $cur\_width \leftarrow second\_width$ ;  $cur\_indent \leftarrow second\_indent$ ;
    end
  else if  $par\_shape\_ptr = null$  then
    begin  $cur\_width \leftarrow first\_width$ ;  $cur\_indent \leftarrow first\_indent$ ;
    end
  else begin  $cur\_width \leftarrow mem[par\_shape\_ptr + 2 * cur\_line].sc$ ;
   $cur\_indent \leftarrow mem[par\_shape\_ptr + 2 * cur\_line - 1].sc$ ;
  end;
   $adjust\_tail \leftarrow adjust\_head$ ;  $just\_box \leftarrow hpack(q, cur\_width, exactly)$ ;  $shift\_amount(just\_box) \leftarrow cur\_indent$ 
```

This code is used in section 891.

**901.** Penalties between the lines of a paragraph come from club and widow lines, from the *inter\_line\_penalty* parameter, and from lines that end at discretionary breaks. Breaking between lines of a two-line paragraph gets both club-line and widow-line penalties. The local variable *pen* will be set to the sum of all relevant penalties for the current line, except that the final line is never penalized.

```

⟨Append a penalty node, if a nonzero penalty is appropriate 901⟩ ≡
  if cur_line + 1 ≠ best_line then
    begin pen ← inter_line_penalty;
    if cur_line = prev_graf + 1 then pen ← pen + club_penalty;
    if cur_line + 2 = best_line then pen ← pen + final_widow_penalty;
    if disc_break then pen ← pen + broken_penalty;
    if pen ≠ 0 then
      begin r ← new_penalty(pen); link(tail) ← r; tail ← r;
      end;
    end

```

This code is used in section 891.

**902. Pre-hyphenation.** When the line-breaking routine is unable to find a feasible sequence of break-points, it makes a second pass over the paragraph, attempting to hyphenate the hyphenatable words. The goal of hyphenation is to insert discretionary material into the paragraph so that there are more potential places to break.

The general rules for hyphenation are somewhat complex and technical, because we want to be able to hyphenate words that are preceded or followed by punctuation marks, and because we want the rules to work for languages other than English. We also must contend with the fact that hyphens might radically alter the ligature and kerning structure of a word.

A sequence of characters will be considered for hyphenation only if it belongs to a “potentially hyphenatable part” of the current paragraph. This is a sequence of nodes  $p_0p_1 \dots p_m$  where  $p_0$  is a glue node,  $p_1 \dots p_{m-1}$  are either character or ligature or whatsit or implicit kern nodes, and  $p_m$  is a glue or penalty or insertion or adjust or mark or whatsit or explicit kern node. (Therefore hyphenation is disabled by boxes, math formulas, and discretionary nodes already inserted by the user.) The ligature nodes among  $p_1 \dots p_{m-1}$  are effectively expanded into the original non-ligature characters; the kern nodes and whatsits are ignored. Each character  $c$  is now classified as either a nonletter (if  $lc\_code(c) = 0$ ), a lowercase letter (if  $lc\_code(c) = c$ ), or an uppercase letter (otherwise); an uppercase letter is treated as if it were  $lc\_code(c)$  for purposes of hyphenation. The characters generated by  $p_1 \dots p_{m-1}$  may begin with nonletters; let  $c_1$  be the first letter that is not in the middle of a ligature. Whatsit nodes preceding  $c_1$  are ignored; a whatsit found after  $c_1$  will be the terminating node  $p_m$ . All characters that do not have the same font as  $c_1$  will be treated as nonletters. The *hyphen\_char* for that font must be between 0 and 255, otherwise hyphenation will not be attempted. T<sub>E</sub>X looks ahead for as many consecutive letters  $c_1 \dots c_n$  as possible; however,  $n$  must be less than 64, so a character that would otherwise be  $c_{64}$  is effectively not a letter. Furthermore  $c_n$  must not be in the middle of a ligature. In this way we obtain a string of letters  $c_1 \dots c_n$  that are generated by nodes  $p_a \dots p_b$ , where  $1 \leq a \leq b + 1 \leq m$ . If  $n \geq Lhyf + rhyf$ , this string qualifies for hyphenation; however, *uc\_hyph* must be positive, if  $c_1$  is uppercase.

The hyphenation process takes place in three stages. First, the candidate sequence  $c_1 \dots c_n$  is found; then potential positions for hyphens are determined by referring to hyphenation tables; and finally, the nodes  $p_a \dots p_b$  are replaced by a new sequence of nodes that includes the discretionary breaks found.

Fortunately, we do not have to do all this calculation very often, because of the way it has been taken out of T<sub>E</sub>X’s inner loop. For example, when the second edition of the author’s 700-page book *Seminumerical Algorithms* was typeset by T<sub>E</sub>X, only about 1.2 hyphenations needed to be tried per paragraph, since the line breaking algorithm needed to use two passes on only about 5 per cent of the paragraphs.

⟨ Initialize for hyphenating a paragraph 902 ⟩ ≡

```
begin init if trie_not_ready then init_trie;
tini
cur_lang ← init_cur_lang; Lhyf ← init_Lhyf; rhyf ← init_rhyf;
end
```

This code is used in section 874.

**903.** The letters  $c_1 \dots c_n$  that are candidates for hyphenation are placed into an array called *hc*; the number *n* is placed into *hn*; pointers to nodes  $p_{a-1}$  and  $p_b$  in the description above are placed into variables *ha* and *hb*; and the font number is placed into *hf*.

```

⟨Global variables 13⟩ +≡
hc: array [0 .. 65] of 0 .. 256; { word to be hyphenated }
hn: small_number; { the number of positions occupied in hc }
ha, hb: pointer; { nodes ha .. hb should be replaced by the hyphenated result }
hf: internal_font_number; { font number of the letters in hc }
hu: array [0 .. 63] of 0 .. 256; { like hc, before conversion to lowercase }
hyf_char: integer; { hyphen character of the relevant font }
cur_lang, init_cur_lang: ASCII_code; { current hyphenation table of interest }
L_hyf, r_hyf, init_L_hyf, init_r_hyf: integer; { limits on fragment sizes }
hyf_bchar: halfword; { boundary character after  $c_n$  }

```

**904.** Hyphenation routines need a few more local variables.

```

⟨Local variables for line breaking 873⟩ +≡
j: small_number; { an index into hc or hu }
c: 0 .. 255; { character being considered for hyphenation }

```

**905.** When the following code is activated, the *line\_break* procedure is in its second pass, and *cur\_p* points to a glue node.

```

⟨Try to hyphenate the following word 905⟩ ≡
begin prev_s ← cur_p; s ← link(prev_s);
if s ≠ null then
  begin ⟨Skip to node ha, or goto done1 if no hyphenation should be attempted 907⟩;
  if L_hyf + r_hyf > 63 then goto done1;
  ⟨Skip to node hb, putting letters into hu and hc 908⟩;
  ⟨Check that the nodes following hb permit hyphenation and that at least L_hyf + r_hyf letters have
    been found, otherwise goto done1 910⟩;
  hyphenate;
  end;
done1: end

```

This code is used in section 877.

**906.** ⟨Declare subprocedures for *line\_break* 837⟩ +≡

```

⟨Declare the function called reconstitute 917⟩
procedure hyphenate;
  label common_ending, done, found, found1, found2, not_found, exit;
  var ⟨Local variables for hyphenation 912⟩
  begin ⟨Find hyphen locations for the word in hc, or return 934⟩;
  ⟨If no hyphens were found, return 913⟩;
  ⟨Replace nodes ha .. hb by a sequence of nodes that includes the discretionary hyphens 914⟩;
exit: end;

```

**907.** The first thing we need to do is find the node *ha* just before the first letter.

⟨Skip to node *ha*, or **goto** *done1* if no hyphenation should be attempted 907⟩ ≡

```

loop begin if is_char_node(s) then
  begin hf ← font(s);
  if font_dir[hf] ≠ dir_default then
    begin prev_s ← s; s ← link(prev_s); c ← info(s); goto continue;
    end
  else c ← qo(character(s));
  end
else if type(s) = disp_node then goto continue
else if (type(s) = penalty_node) ∧ (¬subtype(s) = normal) then goto continue
else if type(s) = ligature_node then
  if lig_ptr(s) = null then goto continue
  else begin q ← lig_ptr(s); c ← qo(character(q)); hf ← font(q);
  end
else if (type(s) = kern_node) ∧ (subtype(s) = normal) then goto continue
else if type(s) = whatsit_node then
  begin ⟨Advance past a whatsit node in the pre-hyphenation loop 1376⟩;
  goto continue;
  end
else goto done1;
if lc_code(c) ≠ 0 then
  if (lc_code(c) = c) ∨ (uc_hyph > 0) then goto done2
  else goto done1;
continue: prev_s ← s; s ← link(prev_s);
end;
done2: hyf_char ← hyphen_char[hf];
if hyf_char < 0 then goto done1;
if hyf_char > 255 then goto done1;
ha ← prev_s

```

This code is used in section 905.

**908.** The word to be hyphenated is now moved to the *hu* and *hc* arrays.

⟨Skip to node *hb*, putting letters into *hu* and *hc* 908⟩ ≡

```

  hn ← 0;
  loop begin if is_char_node(s) then
    begin if font(s) ≠ hf then goto done3;
    hyf_bchar ← character(s); c ← go(hyf_bchar);
    if lc_code(c) = 0 then goto done3;
    if hn = 63 then goto done3;
    hb ← s; incr(hn); hu[hn] ← c; hc[hn] ← lc_code(c); hyf_bchar ← non_char;
    end
  else if type(s) = ligature_node then ⟨Move the characters of a ligature node to hu and hc; but goto
    done3 if they are not all letters 909⟩
  else if (type(s) = kern_node) ∧ (subtype(s) = normal) then
    begin hb ← s; hyf_bchar ← font_bchar[hf];
    end
  else goto done3;
  s ← link(s);
end;
done3:

```

This code is used in section 905.

**909.** We let *j* be the index of the character being stored when a ligature node is being expanded, since we do not want to advance *hn* until we are sure that the entire ligature consists of letters. Note that it is possible to get to *done3* with *hn* = 0 and *hb* not set to any value.

⟨Move the characters of a ligature node to *hu* and *hc*; but goto *done3* if they are not all letters 909⟩ ≡

```

  begin if font(lig_char(s)) ≠ hf then goto done3;
  j ← hn; q ← lig_ptr(s); if q > null then hyf_bchar ← character(q);
  while q > null do
    begin c ← go(character(q));
    if lc_code(c) = 0 then goto done3;
    if j = 63 then goto done3;
    incr(j); hu[j] ← c; hc[j] ← lc_code(c);
    q ← link(q);
    end;
  hb ← s; hn ← j;
  if odd(subtype(s)) then hyf_bchar ← font_bchar[hf] else hyf_bchar ← non_char;
end

```

This code is used in section 908.

**910.** ⟨ Check that the nodes following *hb* permit hyphenation and that at least *l\_hyf* + *r\_hyf* letters have been found, otherwise **goto** *done1* 910) ≡

**end**;

*done4*:

This code is used in section 905.

**911. Post-hyphenation.** If a hyphen may be inserted between  $hc[j]$  and  $hc[j + 1]$ , the hyphenation procedure will set  $hyf[j]$  to some small odd number. But before we look at T<sub>E</sub>X's hyphenation procedure, which is independent of the rest of the line-breaking algorithm, let us consider what we will do with the hyphens it finds, since it is better to work on this part of the program before forgetting what  $ha$  and  $hb$ , etc., are all about.

```

⟨ Global variables 13 ⟩ +=
hyf: array [0 .. 64] of 0 .. 9; { odd values indicate discretionary hyphens }
init_list: pointer; { list of punctuation characters preceding the word }
init_lig: boolean; { does init_list represent a ligature? }
init_lft: boolean; { if so, did the ligature involve a left boundary? }

```

```

912. ⟨ Local variables for hyphenation 912 ⟩ ≡
i, j, l: 0 .. 65; { indices into hc or hu }
q, r, s: pointer; { temporary registers for list manipulation }
bchar: halfword; { right boundary character of hyphenated word, or non_char }

```

See also sections 923, 933, and 940.

This code is used in section 906.

**913.** T<sub>E</sub>X will never insert a hyphen that has fewer than `\lefthyphenmin` letters before it or fewer than `\righthyphenmin` after it; hence, a short word has comparatively little chance of being hyphenated. If no hyphens have been found, we can save time by not having to make any changes to the paragraph.

```

⟨ If no hyphens were found, return 913 ⟩ ≡
for j ← l_hyf to hn - r_hyf do
  if odd(hyf[j]) then goto found1;
return;
found1:

```

This code is used in section 906.

**914.** If hyphens are in fact going to be inserted, T<sub>E</sub>X first deletes the subsequence of nodes between *ha* and *hb*. An attempt is made to preserve the effect that implicit boundary characters and punctuation marks had on ligatures inside the hyphenated word, by storing a left boundary or preceding character in *hu*[0] and by storing a possible right boundary in *bchar*. We set  $j \leftarrow 0$  if *hu*[0] is to be part of the reconstruction; otherwise  $j \leftarrow 1$ . The variable *s* will point to the tail of the current hlist, and *q* will point to the node following *hb*, so that things can be hooked up after we reconstitute the hyphenated word.

```

⟨ Replace nodes ha .. hb by a sequence of nodes that includes the discretionary hyphens 914 ⟩ ≡
  q ← link(hb); link(hb) ← null; r ← link(ha); link(ha) ← null; bchar ← hyf-bchar;

    while link(s) ≠ ha do s ← link(s);
    j ← 0; goto common_ending;
  found2: s ← ha; j ← 0; hu[0] ← 256; init_lig ← false; init_list ← null;
  common_ending: flush_node_list(r);
  ⟨ Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 924 ⟩;
  flush_list(init_list)

```

This code is used in section 906.

**915.** We must now face the fact that the battle is not over, even though the hyphens have been found: The process of reconstituting a word can be nontrivial because ligatures might change when a hyphen is present. *The T<sub>E</sub>Xbook* discusses the difficulties of the word “difficult”, and the discretionary material surrounding a hyphen can be considerably more complex than that. Suppose *abcdef* is a word in a font for which the only ligatures are *bc*, *cd*, *de*, and *ef*. If this word permits hyphenation between *b* and *c*, the two patterns with and without hyphenation are *a b - cd ef* and *a bc de f*. Thus the insertion of a hyphen might cause effects to ripple arbitrarily far into the rest of the word. A further complication arises if additional hyphens appear together with such rippling, e.g., if the word in the example just given could also be hyphenated between *c* and *d*; T<sub>E</sub>X avoids this by simply ignoring the additional hyphens in such weird cases.

Still further complications arise in the presence of ligatures that do not delete the original characters. When punctuation precedes the word being hyphenated, T<sub>E</sub>X’s method is not perfect under all possible scenarios, because punctuation marks and letters can propagate information back and forth. For example, suppose the original pre-hyphenation pair *\*a* changes to *\*y* via a *|=:* ligature, which changes to *xy* via a *=:|* ligature; if  $p_{a-1} = x$  and  $p_a = y$ , the reconstitution procedure isn’t smart enough to obtain *xy* again. In such cases the font designer should include a ligature that goes from *xa* to *xy*.

**916.** The processing is facilitated by a subroutine called *reconstitute*. Given a string of characters  $x_j \dots x_n$ , there is a smallest index  $m \geq j$  such that the “translation” of  $x_j \dots x_n$  by ligatures and kerning has the form  $y_1 \dots y_t$  followed by the translation of  $x_{m+1} \dots x_n$ , where  $y_1 \dots y_t$  is some nonempty sequence of character, ligature, and kern nodes. We call  $x_j \dots x_m$  a “cut prefix” of  $x_j \dots x_n$ . For example, if  $x_1 x_2 x_3 = \text{fl}y$ , and if the font contains ‘fl’ as a ligature and a kern between ‘fl’ and ‘y’, then  $m = 2$ ,  $t = 2$ , and  $y_1$  will be a ligature node for ‘fl’ followed by an appropriate kern node  $y_2$ . In the most common case,  $x_j$  forms no ligature with  $x_{j+1}$  and we simply have  $m = j$ ,  $y_1 = x_j$ . If  $m < n$  we can repeat the procedure on  $x_{m+1} \dots x_n$  until the entire translation has been found.

The *reconstitute* function returns the integer  $m$  and puts the nodes  $y_1 \dots y_t$  into a linked list starting at *link(hold\_head)*, getting the input  $x_j \dots x_n$  from the *hu* array. If  $x_j = 256$ , we consider  $x_j$  to be an implicit left boundary character; in this case  $j$  must be strictly less than  $n$ . There is a parameter *bchar*, which is either 256 or an implicit right boundary character assumed to be present just following  $x_n$ . (The value *hu*[ $n + 1$ ] is never explicitly examined, but the algorithm imagines that *bchar* is there.)

If there exists an index  $k$  in the range  $j \leq k \leq m$  such that *hyf*[ $k$ ] is odd and such that the result of *reconstitute* would have been different if  $x_{k+1}$  had been *hchar*, then *reconstitute* sets *hyphen-passed* to the smallest such  $k$ . Otherwise it sets *hyphen-passed* to zero.

A special convention is used in the case  $j = 0$ : Then we assume that the translation of *hu*[0] appears in a special list of charnodes starting at *init\_list*; moreover, if *init\_lig* is *true*, then *hu*[0] will be a ligature character, involving a left boundary if *init\_lft* is *true*. This facility is provided for cases when a hyphenated word is preceded by punctuation (like single or double quotes) that might affect the translation of the beginning of the word.

⟨Global variables 13⟩ +≡

*hyphen-passed*: *small\_number*; { first hyphen in a ligature, if any }

**917.** ⟨Declare the function called *reconstitute* 917⟩ ≡

⟨Append a ligature and/or kern to the translation; **goto** *continue* if the stack of inserted ligatures is nonempty 921⟩;

*reconstitute* ← *j*;

**end**;

This code is used in section 906.

**918.** The reconstitution procedure shares many of the global data structures by which T<sub>E</sub>X has processed the words before they were hyphenated. There is an implied “cursor” between characters *cur\_l* and *cur\_r*; these characters will be tested for possible ligature activity. If *ligature\_present* then *cur\_l* is a ligature character formed from the original characters following *cur\_q* in the current translation list. There is a “ligature stack” between the cursor and character *j + 1*, consisting of pseudo-ligature nodes linked together by their *link* fields. This stack is normally empty unless a ligature command has created a new character that will need to be processed later. A pseudo-ligature is a special node having a *character* field that represents a potential ligature and a *lig\_ptr* field that points to a *char\_node* or is *null*. We have

$$cur_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ qi(hu[j+1]), & \text{if } lig\_stack = null \text{ and } j < n; \\ bchar, & \text{if } lig\_stack = null \text{ and } j = n. \end{cases}$$

This code is used in section 920.

**923.** Okay, we're ready to insert the potential hyphenations that were found. When the following program is executed, we want to append the word *hu*[1 .. *hn*] after node *ha*, and node *q* should be appended to the result. During this process, the variable *i* will be a temporary index into *hu*; the variable *j* will be an index to our current position in *hu*; the variable *l* will be the counterpart of *j*, in a discretionary branch; the variable *r* will point to new nodes being created; and we need a few new local variables:

```

⟨Local variables for hyphenation 912⟩ +≡
major_tail, minor_tail: pointer;
    { the end of lists in the main and discretionary branches being reconstructed }
c: ASCII_code; { character temporarily replaced by a hyphen }
c_loc: 0 .. 63; { where that character came from }
r_count: integer; { replacement count for discretionary }
hyf_node: pointer; { the hyphen, if it exists }

```

**924.** When the following code is performed,  $hyf[0]$  and  $hyf[hn]$  will be zero.

⟨Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 924⟩ ≡

```

repeat  $l \leftarrow j$ ;  $j \leftarrow reconstitute(j, hn, bchar, qi(hyf\_char)) + 1$ ;
  if  $hyphen\_passed = 0$  then
    begin  $link(s) \leftarrow link(hold\_head)$ ;
    while  $link(s) > null$  do  $s \leftarrow link(s)$ ;
    if  $odd(hyf[j - 1])$  then
      begin  $l \leftarrow j$ ;  $hyphen\_passed \leftarrow j - 1$ ;  $link(hold\_head) \leftarrow null$ ;
      end;
    end;
  if  $hyphen\_passed > 0$  then ⟨Create and append a discretionary node as an alternative to the
    unhyphenated word, and continue to develop both branches until they become equivalent 925⟩;
until  $j > hn$ ;
 $link(s) \leftarrow q$ 

```

This code is used in section 914.

**925.** In this repeat loop we will insert another discretionary if  $hyf[j - 1]$  is odd, when both branches of the previous discretionary end at position  $j - 1$ . Strictly speaking, we aren't justified in doing this, because we don't know that a hyphen after  $j - 1$  is truly independent of those branches. But in almost all applications we would rather not lose a potentially valuable hyphenation point. (Consider the word 'difficult', where the letter 'c' is in position  $j$ .)

```

define  $advance\_major\_tail \equiv$ 
  begin  $major\_tail \leftarrow link(major\_tail)$ ;  $incr(r\_count)$ ;
  end

```

⟨Create and append a discretionary node as an alternative to the unhyphenated word, and continue to develop both branches until they become equivalent 925⟩ ≡

```

repeat  $r \leftarrow get\_node(small\_node\_size)$ ;  $link(r) \leftarrow link(hold\_head)$ ;  $type(r) \leftarrow disc\_node$ ;  $major\_tail \leftarrow r$ ;
   $r\_count \leftarrow 0$ ;
  while  $link(major\_tail) > null$  do  $advance\_major\_tail$ ;
   $i \leftarrow hyphen\_passed$ ;  $hyf[i] \leftarrow 0$ ; ⟨Put the characters  $hu[l \dots i]$  and a hyphen into  $pre\_break(r)$  926⟩;
  ⟨Put the characters  $hu[i + 1 \dots ]$  into  $post\_break(r)$ , appending to this list and to  $major\_tail$  until
    synchronization has been achieved 927⟩;
  ⟨Move pointer  $s$  to the end of the current list, and set  $replace\_count(r)$  appropriately 929⟩;
   $hyphen\_passed \leftarrow j - 1$ ;  $link(hold\_head) \leftarrow null$ ;
until  $\neg odd(hyf[j - 1])$ 

```

This code is used in section 924.

**926.** The new hyphen might combine with the previous character via ligature or kern. At this point we have  $l - 1 \leq i < j$  and  $i < hn$ .

```

⟨Put the characters  $hu[l \dots i]$  and a hyphen into  $pre\_break(r)$  926⟩ ≡
   $minor\_tail \leftarrow null$ ;  $pre\_break(r) \leftarrow null$ ;  $hyf\_node \leftarrow new\_character(hf, hyf\_char)$ ;
  if  $hyf\_node \neq null$  then
    begin  $incr(i)$ ;  $c \leftarrow hu[i]$ ;  $hu[i] \leftarrow hyf\_char$ ;  $free\_avail(hyf\_node)$ ;
    end;
  while  $l \leq i$  do
    begin  $l \leftarrow reconstitute(l, i, font\_bchar[hf], non\_char) + 1$ ;
    if  $link(hold\_head) > null$  then
      begin if  $minor\_tail = null$  then  $pre\_break(r) \leftarrow link(hold\_head)$ 
      else  $link(minor\_tail) \leftarrow link(hold\_head)$ ;
       $minor\_tail \leftarrow link(hold\_head)$ ;
      while  $link(minor\_tail) > null$  do  $minor\_tail \leftarrow link(minor\_tail)$ ;
      end;
    end;
  if  $hyf\_node \neq null$  then
    begin  $hu[i] \leftarrow c$ ; { restore the character in the hyphen position }
     $l \leftarrow i$ ;  $decr(i)$ ;
    end

```

This code is used in section 925.

**927.** The synchronization algorithm begins with  $l = i + 1 \leq j$ .

```

⟨Put the characters  $hu[i + 1 \dots j]$  into  $post\_break(r)$ , appending to this list and to  $major\_tail$  until
synchronization has been achieved 927⟩ ≡
   $minor\_tail \leftarrow null$ ;  $post\_break(r) \leftarrow null$ ;  $c\_loc \leftarrow 0$ ;
  if  $bchar\_label[hf] \neq non\_address$  then { put left boundary at beginning of new line }
    begin  $decr(l)$ ;  $c \leftarrow hu[l]$ ;  $c\_loc \leftarrow l$ ;  $hu[l] \leftarrow 256$ ;
    end;
  while  $l < j$  do
    begin repeat  $l \leftarrow reconstitute(l, hn, bchar, non\_char) + 1$ ;
    if  $c\_loc > 0$  then
      begin  $hu[c\_loc] \leftarrow c$ ;  $c\_loc \leftarrow 0$ ;
      end;
    if  $link(hold\_head) > null$  then
      begin if  $minor\_tail = null$  then  $post\_break(r) \leftarrow link(hold\_head)$ 
      else  $link(minor\_tail) \leftarrow link(hold\_head)$ ;
       $minor\_tail \leftarrow link(hold\_head)$ ;
      while  $link(minor\_tail) > null$  do  $minor\_tail \leftarrow link(minor\_tail)$ ;
      end;
    until  $l \geq j$ ;
    while  $l > j$  do ⟨Append characters of  $hu[j \dots j]$  to  $major\_tail$ , advancing  $j$  928⟩;
    end

```

This code is used in section 925.

```

928. ⟨Append characters of  $hu[j \dots j]$  to  $major\_tail$ , advancing  $j$  928⟩ ≡
  begin  $j \leftarrow reconstitute(j, hn, bchar, non\_char) + 1$ ;  $link(major\_tail) \leftarrow link(hold\_head)$ ;
  while  $link(major\_tail) > null$  do  $advance\_major\_tail$ ;
  end

```

This code is used in section 927.

**929.** Ligature insertion can cause a word to grow exponentially in size. Therefore we must test the size of *r\_count* here, even though the hyphenated text was at most 63 characters long.

```
< Move pointer s to the end of the current list, and set replace_count(r) appropriately 929 > ≡  
  if r_count > 127 then { we have to forget the discretionary hyphen }  
    begin link(s) ← link(r); link(r) ← null; flush_node_list(r);  
    end  
  else begin link(s) ← r; replace_count(r) ← r_count;  
  end;  
  s ← major_tail
```

This code is used in section 925.

**930. Hyphenation.** When a word  $hc[1..hn]$  has been set up to contain a candidate for hyphenation, T<sub>E</sub>X first looks to see if it is in the user’s exception dictionary. If not, hyphens are inserted based on patterns that appear within the given word, using an algorithm due to Frank M. Liang.

Let’s consider Liang’s method first, since it is much more interesting than the exception-lookup routine. The algorithm begins by setting  $hyf[j]$  to zero for all  $j$ , and invalid characters are inserted into  $hc[0]$  and  $hc[hn+1]$  to serve as delimiters. Then a reasonably fast method is used to see which of a given set of patterns occurs in the word  $hc[0..(hn+1)]$ . Each pattern  $p_1..p_k$  of length  $k$  has an associated sequence of  $k+1$  numbers  $n_0..n_k$ ; and if the pattern occurs in  $hc[(j+1)..(j+k)]$ , T<sub>E</sub>X will set  $hyf[j+i] \leftarrow \max(hyf[j+i], n_i)$  for  $0 \leq i \leq k$ . After this has been done for each pattern that occurs, a discretionary hyphen will be inserted between  $hc[j]$  and  $hc[j+1]$  when  $hyf[j]$  is odd, as we have already seen.

The set of patterns  $p_1..p_k$  and associated numbers  $n_0..n_k$  depends, of course, on the language whose words are being hyphenated, and on the degree of hyphenation that is desired. A method for finding appropriate  $p$ ’s and  $n$ ’s, from a given dictionary of words and acceptable hyphenations, is discussed in Liang’s Ph.D. thesis (Stanford University, 1983); T<sub>E</sub>X simply starts with the patterns and works from there.

**931.** The patterns are stored in a compact table that is also efficient for retrieval, using a variant of “trie memory” [cf. *The Art of Computer Programming* 3 (1973), 481–505]. We can find each pattern  $p_1..p_k$  by letting  $z_0$  be one greater than the relevant language index and then, for  $1 \leq i \leq k$ , setting  $z_i \leftarrow trie\_link(z_{i-1}) + p_i$ ; the pattern will be identified by the number  $z_k$ . Since all the pattern information is packed together into a single *trie\_link* array, it is necessary to prevent confusion between the data from inequivalent patterns, so another table is provided such that  $trie\_char(z_i) = p_i$  for all  $i$ . There is also a table *trie\_op*( $z_k$ ) to identify the numbers  $n_0..n_k$  associated with  $p_1..p_k$ .

The theory that comparatively few different number sequences  $n_0..n_k$  actually occur, since most of the  $n$ ’s are generally zero, seems to fail at least for the large German hyphenation patterns. Therefore the number sequences cannot any longer be encoded in such a way that *trie\_op*( $z_k$ ) is only one byte long. We have introduced a new constant *max\_trie\_op* for the maximum allowable hyphenation operation code value; *max\_trie\_op* might be different for T<sub>E</sub>X and INITEX and must not exceed *max\_halfword*. An opcode will occupy a halfword if *max\_trie\_op* exceeds *max\_quarterword* or a quarterword otherwise. If  $trie\_op(z_k) \neq min\_trie\_op$ , when  $p_1..p_k$  has matched the letters in  $hc[(l-k+1)..l]$  of language  $t$ , we perform all of the required operations for this pattern by carrying out the following little program: Set  $v \leftarrow trie\_op(z_k)$ . Then set  $v \leftarrow v + op\_start[t]$ ,  $hyf[l - hyf\_distance[v]] \leftarrow \max(hyf[l - hyf\_distance[v]], hyf\_num[v])$ , and  $v \leftarrow hyf\_next[v]$ ; repeat, if necessary, until  $v = min\_trie\_op$ .

```
<Types in the outer block 18> +=
  trie_pointer = 0 .. ssup_trie_size; { an index into trie }
  trie_opcode = 0 .. ssup_trie_opcode; { a trie opcode }
```

**932.** For more than 255 trie op codes, the three fields *trie\_link*, *trie\_char*, and *trie\_op* will no longer fit into one memory word; thus using web2c we define *trie* as three array instead of an array of records. The variant will be implemented by reusing the opcode field later on with another macro.

```
define trie_link(#) ≡ trie_trl[#] { “downward” link in a trie }
define trie_char(#) ≡ trie_trc[#] { character matched at this trie location }
define trie_op(#) ≡ trie_tro[#] { program for hyphenation at this trie location }
```

```
<Global variables 13> +=
  { We will dynamically allocate these arrays. }
trie_trl: ↑trie_pointer; { trie_link }
trie_tro: ↑trie_pointer; { trie_op }
trie_trc: ↑quarterword; { trie_char }
hyf_distance: array [1 .. trie_op_size] of small_number; { position k - j of n_j }
hyf_num: array [1 .. trie_op_size] of small_number; { value of n_j }
hyf_next: array [1 .. trie_op_size] of trie_opcode; { continuation code }
op_start: array [ASCII_code] of 0 .. trie_op_size; { offset for current language }
```

**933.**  $\langle$  Local variables for hyphenation 912  $\rangle + \equiv$

$z$ : *trie\_pointer*; { an index into *trie* }  
 $v$ : *integer*; { an index into *hyf\_distance*, etc. }

**934.** Assuming that these auxiliary tables have been set up properly, the hyphenation algorithm is quite short. In the following code we set  $hc[hn + 2]$  to the impossible value 256, in order to guarantee that  $hc[hn + 3]$  will never be fetched.

```

 $\langle$  Find hyphen locations for the word in  $hc$ , or return 934  $\rangle \equiv$ 
  for  $j \leftarrow 0$  to  $hn$  do  $hyf[j] \leftarrow 0$ ;
   $\langle$  Look for the word  $hc[1 .. hn]$  in the exception table, and goto found (with hyf containing the hyphens)
  if an entry is found 941  $\rangle$ ;
  if  $trie\_char(cur\_lang + 1) \neq qi(cur\_lang)$  then return; { no patterns for cur_lang }
   $hc[0] \leftarrow 0$ ;  $hc[hn + 1] \leftarrow 0$ ;  $hc[hn + 2] \leftarrow 256$ ; { insert delimiters }
  for  $j \leftarrow 0$  to  $hn - r\_hyf + 1$  do
    begin  $z \leftarrow trie\_link(cur\_lang + 1) + hc[j]$ ;  $l \leftarrow j$ ;
    while  $hc[l] = qo(trie\_char(z))$  do
      begin if  $trie\_op(z) \neq min\_trie\_op$  then  $\langle$  Store maximum values in the hyf table 935  $\rangle$ ;
         $incr(l)$ ;  $z \leftarrow trie\_link(z) + hc[l]$ ;
      end;
    end;
  found: for  $j \leftarrow 0$  to  $l\_hyf - 1$  do  $hyf[j] \leftarrow 0$ ;
  for  $j \leftarrow 0$  to  $r\_hyf - 1$  do  $hyf[hn - j] \leftarrow 0$ 

```

This code is used in section 906.

**935.**  $\langle$  Store maximum values in the *hyf* table 935  $\rangle \equiv$

```

  begin  $v \leftarrow trie\_op(z)$ ;
  repeat  $v \leftarrow v + op\_start[cur\_lang]$ ;  $i \leftarrow l - hyf\_distance[v]$ ;
    if  $hyf\_num[v] > hyf[i]$  then  $hyf[i] \leftarrow hyf\_num[v]$ ;
     $v \leftarrow hyf\_next[v]$ ;
  until  $v = min\_trie\_op$ ;
  end

```

This code is used in section 934.

**936.** The exception table that is built by T<sub>E</sub>X's `\hyphenation` primitive is organized as an ordered hash table [cf. Amble and Knuth, *The Computer Journal* **17** (1974), 135–142] using linear probing. If  $\alpha$  and  $\beta$  are words, we will say that  $\alpha < \beta$  if  $|\alpha| < |\beta|$  or if  $|\alpha| = |\beta|$  and  $\alpha$  is lexicographically smaller than  $\beta$ . (The notation  $|\alpha|$  stands for the length of  $\alpha$ .) The idea of ordered hashing is to arrange the table so that a given word  $\alpha$  can be sought by computing a hash address  $h = h(\alpha)$  and then looking in table positions  $h, h - 1, \dots$ , until encountering the first word  $\leq \alpha$ . If this word is different from  $\alpha$ , we can conclude that  $\alpha$  is not in the table. This is a clever scheme which saves the need for a hash link array. However, it is difficult to increase the size of the hyphen exception arrays. To make this easier, the ordered hash has been replaced by a simple hash, using an additional array *hyph\_link*. The value 0 in *hyph\_link*[ $k$ ] means that there are no more entries corresponding to the specific hash chain. When *hyph\_link*[ $k$ ]  $> 0$ , the next entry in the hash chain is *hyph\_link*[ $k$ ]  $- 1$ . This value is used because the arrays start at 0.

The words in the table point to lists in *mem* that specify hyphen positions in their *info* fields. The list for  $c_1 \dots c_n$  contains the number  $k$  if the word  $c_1 \dots c_n$  has a discretionary hyphen between  $c_k$  and  $c_{k+1}$ .

$\langle$  Types in the outer block 18  $\rangle + \equiv$

```

   $hyph\_pointer = 0 .. ssup\_hyph\_size$ ;
  { index into hyphen exceptions hash table; enlarging this requires changing (un)dump code }

```

**937.** ⟨Global variables 13⟩ +≡

*hyph\_word*: ↑*str\_number*; {exception words}  
*hyph\_list*: ↑*pointer*; {lists of hyphen positions}  
*hyph\_link*: ↑*hyph\_pointer*; {link array for hyphen exceptions hash table}  
*hyph\_count*: *integer*; {the number of words in the exception dictionary}  
*hyph\_next*: *integer*; {next free slot in hyphen exceptions hash table}

**938.** ⟨Local variables for initialization 19⟩ +≡

*z*: *hyph\_pointer*; {runs through the exception dictionary}

**939.** ⟨Set initial values of key variables 21⟩ +≡

```

for z ← 0 to hyph_size do
  begin hyph_word[z] ← 0; hyph_list[z] ← null; hyph_link[z] ← 0;
  end;
hyph_count ← 0; hyph_next ← hyph_prime + 1;
if hyph_next > hyph_size then hyph_next ← hyph_prime;

```

**940.** The algorithm for exception lookup is quite simple, as soon as we have a few more local variables to work with.

⟨Local variables for hyphenation 912⟩ +≡

*h*: *hyph\_pointer*; {an index into *hyph\_word* and *hyph\_list*}  
*k*: *str\_number*; {an index into *str\_start*}  
*u*: *pool\_pointer*; {an index into *str\_pool*}

**941.** First we compute the hash code *h*, then we search until we either find the word or we don't. Words from different languages are kept separate by appending the language code to the string.

⟨Look for the word *hc*[1 .. *hn*] in the exception table, and **goto** *found* (with *hyf* containing the hyphens) if an entry is found 941⟩ ≡

```

h ← hc[1]; incr(hn); hc[hn] ← cur_lang;
for j ← 2 to hn do h ← (h + h + hc[j]) mod hyph_prime;
loop begin ⟨If the string hyph_word[h] is less than hc[1 .. hn], goto not_found; but if the two strings
  are equal, set hyf to the hyphen positions and goto found 942);
  h ← hyph_link[h];
  if h = 0 then goto not_found;
  decr(h);
end;
not_found: decr(hn)

```

This code is used in section 934.

**942.**  $\langle$  If the string *hyph\_word*[*h*] is less than *hc*[1 .. *hn*], **goto** *not\_found*; but if the two strings are equal, set *hyf* to the hyphen positions and **goto** *found* 942  $\rangle \equiv$   
 { This is now a simple hash list, not an ordered one, so the module title is no longer descriptive. }

**953. Initializing the hyphenation tables.** The trie for T<sub>E</sub>X's hyphenation algorithm is built from a sequence of patterns following a `\patterns` specification. Such a specification is allowed only in INITEX, since the extra memory for auxiliary tables and for the initialization program itself would only clutter up the production version of T<sub>E</sub>X with a lot of deadwood.

The first step is to build a trie that is linked, instead of packed into sequential storage, so that insertions are readily made. After all patterns have been processed, INITEX compresses the linked trie by identifying common subtrees. Finally the trie is packed into the efficient sequential form that the hyphenation algorithm actually uses.

```

⟨Declare subprocedures for line_break 837⟩ +≡
  init ⟨Declare procedures for preprocessing hyphenation patterns 955⟩
  tini

```

**954.** Before we discuss trie building in detail, let's consider the simpler problem of creating the *hyf\_distance*, *hyf\_num*, and *hyf\_next* arrays.

Suppose, for example, that T<sub>E</sub>X reads the pattern 'ab2cde1'. This is a pattern of length 5, with  $n_0 \dots n_5 = 002001$  in the notation above. We want the corresponding *trie\_op* code  $v$  to have  $hyf\_distance[v] = 3$ ,  $hyf\_num[v] = 2$ , and  $hyf\_next[v] = v'$ , where the auxiliary *trie\_op* code  $v'$  has  $hyf\_distance[v'] = 0$ ,  $hyf\_num[v'] = 1$ , and  $hyf\_next[v'] = min\_trie\_op$ .

T<sub>E</sub>X computes an appropriate value  $v$  with the *new\_trie\_op* subroutine below, by setting

$$v' \leftarrow new\_trie\_op(0, 1, min\_trie\_op), \quad v \leftarrow new\_trie\_op(3, 2, v').$$

This subroutine looks up its three parameters in a special hash table, assigning a new value only if these three have not appeared before for the current language.

The hash table is called *trie\_op\_hash*, and the number of entries it contains is *trie\_op\_ptr*.

```

⟨Global variables 13⟩ +≡
  init trie_op_hash: array [neg_trie_op_size .. trie_op_size] of 0 .. trie_op_size;
    { trie op codes for quadruples }
  trie_used: array [ASCII_code] of trie_opcode; { largest opcode used so far for this language }
  trie_op_lang: array [1 .. trie_op_size] of ASCII_code; { language part of a hashed quadruple }
  trie_op_val: array [1 .. trie_op_size] of trie_opcode; { opcode corresponding to a hashed quadruple }
  trie_op_ptr: 0 .. trie_op_size; { number of stored ops so far }
  tini
  max_op_used: trie_opcode; { largest opcode used for any language }
  small_op: boolean; { flag used while dumping or undumping }

```

**955.** It's tempting to remove the *overflow* stops in the following procedure; *new\_trie\_op* could return *min\_trie\_op* (thereby simply ignoring part of a hyphenation pattern) instead of aborting the job. However, that would lead to different hyphenation results on different installations of TEX using the same patterns. The *overflow* stops are necessary for portability of patterns.

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ ≡

```
function new_trie_op(d, n : small_number; v : trie_opcode): trie_opcode;
  label exit;
  var h: neg_trie_op_size .. trie_op_size; { trial hash location }
      u: trie_opcode; { trial op code }
      l: 0 .. trie_op_size; { pointer to stored data }
  begin h ← abs(intcast(n) + 313 * intcast(d) + 361 * intcast(v) + 1009 * intcast(cur_lang)) mod
      (trie_op_size - neg_trie_op_size) + neg_trie_op_size;
  loop begin l ← trie_op_hash[h];
    if l = 0 then { empty position found for a new op }
      begin if trie_op_ptr = trie_op_size then overflow("pattern_memory_ops", trie_op_size);
        u ← trie_used[cur_lang];
        if u = max_trie_op then
          overflow("pattern_memory_ops_per_language", max_trie_op - min_trie_op);
          incr(trie_op_ptr); incr(u); trie_used[cur_lang] ← u;
          if u > max_op_used then max_op_used ← u;
          hyf_distance[trie_op_ptr] ← d; hyf_num[trie_op_ptr] ← n; hyf_next[trie_op_ptr] ← v;
          trie_op_lang[trie_op_ptr] ← cur_lang; trie_op_hash[h] ← trie_op_ptr; trie_op_val[trie_op_ptr] ← u;
          new_trie_op ← u; return;
        end;
      if (hyf_distance[l] = d) ∧ (hyf_num[l] = n) ∧ (hyf_next[l] = v) ∧ (trie_op_lang[l] = cur_lang) then
        begin new_trie_op ← trie_op_val[l]; return;
        end;
      if h > -trie_op_size then decr(h) else h ← trie_op_size;
    end;
  exit: end;
```

See also sections 959, 960, 964, 968, 970, 971, and 977.

This code is used in section 953.

**956.** After *new\_trie\_op* has compressed the necessary opcode information, plenty of information is available to unscramble the data into the final form needed by our hyphenation algorithm.

⟨Sort the hyphenation op tables into proper order 956⟩ ≡

```
op_start[0] ← -min_trie_op;
for j ← 1 to 255 do op_start[j] ← op_start[j - 1] + qo(trie_used[j - 1]);
for j ← 1 to trie_op_ptr do trie_op_hash[j] ← op_start[trie_op_lang[j]] + trie_op_val[j]; { destination }
for j ← 1 to trie_op_ptr do
  while trie_op_hash[j] > j do
    begin k ← trie_op_hash[j];
      t ← hyf_distance[k]; hyf_distance[k] ← hyf_distance[j]; hyf_distance[j] ← t;
      t ← hyf_num[k]; hyf_num[k] ← hyf_num[j]; hyf_num[j] ← t;
      t ← hyf_next[k]; hyf_next[k] ← hyf_next[j]; hyf_next[j] ← t;
      trie_op_hash[j] ← trie_op_hash[k]; trie_op_hash[k] ← j;
    end
```

This code is used in section 963.

**957.** Before we forget how to initialize the data structures that have been mentioned so far, let's write down the code that gets them started.

```

⟨ Initialize table entries (done by INITEX only) 170 ⟩ +=
  for  $k \leftarrow -trie\_op\_size$  to  $trie\_op\_size$  do  $trie\_op\_hash[k] \leftarrow 0$ ;
  for  $k \leftarrow 0$  to 255 do  $trie\_used[k] \leftarrow min\_trie\_op$ ;
   $max\_op\_used \leftarrow min\_trie\_op$ ;  $trie\_op\_ptr \leftarrow 0$ ;

```

**958.** The linked trie that is used to preprocess hyphenation patterns appears in several global arrays. Each node represents an instruction of the form “if you see character  $c$ , then perform operation  $o$ , move to the next character, and go to node  $l$ ; otherwise go to node  $r$ .” The four quantities  $c$ ,  $o$ ,  $l$ , and  $r$  are stored in four arrays  $trie\_c$ ,  $trie\_o$ ,  $trie\_l$ , and  $trie\_r$ . The root of the trie is  $trie\_l[0]$ , and the number of nodes is  $trie\_ptr$ . Null trie pointers are represented by zero. To initialize the trie, we simply set  $trie\_l[0]$  and  $trie\_ptr$  to zero. We also set  $trie\_c[0]$  to some arbitrary value, since the algorithm may access it.

The algorithms maintain the condition

$$trie\_c[trie\_r[z]] > trie\_c[z] \quad \text{whenever } z \neq 0 \text{ and } trie\_r[z] \neq 0;$$

in other words, sibling nodes are ordered by their  $c$  fields.

**define**  $trie\_root \equiv trie\_l[0]$  { root of the linked trie }

⟨ Global variables 13 ⟩ +=

```

init  $trie\_c$ :  $\uparrow packed\_ASCII\_code$ ; { characters to match }
 $trie\_o$ :  $\uparrow trie\_opcode$ ; { operations to perform }
 $trie\_l$ :  $\uparrow trie\_pointer$ ; { left subtrie links }
 $trie\_r$ :  $\uparrow trie\_pointer$ ; { right subtrie links }
 $trie\_ptr$ :  $trie\_pointer$ ; { the number of nodes in the trie }
 $trie\_hash$ :  $\uparrow trie\_pointer$ ; { used to identify equivalent subtrees }
tini

```

**959.** Let us suppose that a linked trie has already been constructed. Experience shows that we can often reduce its size by recognizing common subtrees; therefore another hash table is introduced for this purpose, somewhat similar to *trie\_op\_hash*. The new hash table will be initialized to zero.

The function *trie\_node*(*p*) returns *p* if *p* is distinct from other nodes that it has seen, otherwise it returns the number of the first equivalent node that it has seen.

Notice that we might make subtrees equivalent even if they correspond to patterns for different languages, in which the trie ops might mean quite different things. That's perfectly all right.

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +≡

```
function trie_node(p : trie_pointer): trie_pointer; { converts to a canonical form }
  label exit;
  var h: trie_pointer; { trial hash location }
      q: trie_pointer; { trial trie node }
  begin h ← abs(intcast(trie_c[p]) + 1009 * intcast(trie_o[p]) +
    2718 * intcast(trie_l[p]) + 3142 * intcast(trie_r[p])) mod trie_size;
  loop begin q ← trie_hash[h];
    if q = 0 then
      begin trie_hash[h] ← p; trie_node ← p; return;
      end;
    if (trie_c[q] = trie_c[p]) ∧ (trie_o[q] = trie_o[p]) ∧ (trie_l[q] = trie_l[p]) ∧ (trie_r[q] = trie_r[p]) then
      begin trie_node ← q; return;
      end;
    if h > 0 then decr(h) else h ← trie_size;
    end;
  exit: end;
```

**960.** A neat recursive procedure is now able to compress a trie by traversing it and applying *trie\_node* to its nodes in “bottom up” fashion. We will compress the entire trie by clearing *trie\_hash* to zero and then saying ‘*trie\_root* ← *compress\_trie*(*trie\_root*)’.

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +≡

```
function compress_trie(p : trie_pointer): trie_pointer;
  begin if p = 0 then compress_trie ← 0
  else begin trie_l[p] ← compress_trie(trie_l[p]); trie_r[p] ← compress_trie(trie_r[p]);
    compress_trie ← trie_node(p);
  end;
end;
```

**961.** The compressed trie will be packed into the *trie* array using a “top-down first-fit” procedure. This is a little tricky, so the reader should pay close attention: The *trie\_hash* array is cleared to zero again and renamed *trie\_ref* for this phase of the operation; later on, *trie\_ref*[*p*] will be nonzero only if the linked trie node *p* is the smallest character in a family and if the characters *c* of that family have been allocated to locations *trie\_ref*[*p*] + *c* in the *trie* array. Locations of *trie* that are in use will have *trie\_link* = 0, while the unused holes in *trie* will be doubly linked with *trie\_link* pointing to the next larger vacant location and *trie\_back* pointing to the next smaller one. This double linking will have been carried out only as far as *trie\_max*, where *trie\_max* is the largest index of *trie* that will be needed. To save time at the low end of the trie, we maintain array entries *trie\_min*[*c*] pointing to the smallest hole that is greater than *c*. Another array *trie\_taken* tells whether or not a given location is equal to *trie\_ref*[*p*] for some *p*; this array is used to ensure that distinct nodes in the compressed trie will have distinct *trie\_ref* entries.

```
define trie_ref ≡ trie_hash { where linked trie families go into trie }
define trie_back(#) ≡ trie_tro[#] { use the opcode field now for backward links }
```

⟨ Global variables 13 ⟩ +=

```
init trie_taken: ↑boolean; { does a family start here? }
trie_min: array [ASCII_code] of trie_pointer; { the first possible slot for each character }
trie_max: trie_pointer; { largest location used in trie }
trie_not_ready: boolean; { is the trie still in linked form? }
tini
```

**962.** Each time `\patterns` appears, it contributes further patterns to the future trie, which will be built only when hyphenation is attempted or when a format file is dumped. The boolean variable *trie\_not\_ready* will change to *false* when the trie is compressed; this will disable further patterns.

⟨ Initialize table entries (done by INITEX only) 170 ⟩ +=

```
trie_not_ready ← true;
```

**963.** Here is how the trie-compression data structures are initialized. If storage is tight, it would be possible to overlap *trie\_op\_hash*, *trie\_op\_lang*, and *trie\_op\_val* with *trie*, *trie\_hash*, and *trie\_taken*, because we finish with the former just before we need the latter.

⟨ Get ready to compress the trie 963 ⟩ ≡

```
⟨ Sort the hyphenation op tables into proper order 956 ⟩;
for p ← 0 to trie_size do trie_hash[p] ← 0;
trie_root ← compress_trie(trie_root); { identify equivalent subtrees }
for p ← 0 to trie_ptr do trie_ref[p] ← 0;
for p ← 0 to 255 do trie_min[p] ← p + 1;
trie_link(0) ← 1; trie_max ← 0
```

This code is used in section 977.

**964.** The *first\_fit* procedure finds the smallest hole  $z$  in *trie* such that a trie family starting at a given node  $p$  will fit into vacant positions starting at  $z$ . If  $c = \text{trie}_c[p]$ , this means that location  $z - c$  must not already be taken by some other family, and that  $z - c + c'$  must be vacant for all characters  $c'$  in the family. The procedure sets  $\text{trie\_ref}[p]$  to  $z - c$  when the first fit has been found.

```

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +=
procedure first_fit( $p : \text{trie\_pointer}$ ); { packs a family into trie }
  label not_found, found;
  var  $h : \text{trie\_pointer}$ ; { candidate for  $\text{trie\_ref}[p]$  }
       $z : \text{trie\_pointer}$ ; { runs through holes }
       $q : \text{trie\_pointer}$ ; { runs through the family starting at  $p$  }
       $c : \text{ASCII\_code}$ ; { smallest character in the family }
       $l, r : \text{trie\_pointer}$ ; { left and right neighbors }
       $ll : 1 .. 256$ ; { upper limit of  $\text{trie\_min}$  updating }
  begin  $c \leftarrow \text{so}(\text{trie}_c[p])$ ;  $z \leftarrow \text{trie\_min}[c]$ ; { get the first conceivably good hole }
  loop begin  $h \leftarrow z - c$ ;
    ⟨Ensure that  $\text{trie\_max} \geq h + 256$  965⟩;
    if  $\text{trie\_taken}[h]$  then goto not_found;
    ⟨If all characters of the family fit relative to  $h$ , then goto found, otherwise goto not_found 966⟩;
    not_found:  $z \leftarrow \text{trie\_link}(z)$ ; { move to the next hole }
  end;
found: ⟨Pack the family into trie relative to  $h$  967⟩;
end;

```

**965.** By making sure that  $\text{trie\_max}$  is at least  $h + 256$ , we can be sure that  $\text{trie\_max} > z$ , since  $h = z - c$ . It follows that location  $\text{trie\_max}$  will never be occupied in *trie*, and we will have  $\text{trie\_max} \geq \text{trie\_link}(z)$ .

```

⟨Ensure that  $\text{trie\_max} \geq h + 256$  965⟩ ≡
if  $\text{trie\_max} < h + 256$  then
  begin if  $\text{trie\_size} \leq h + 256$  then overflow("pattern_memory",  $\text{trie\_size}$ );
  repeat  $\text{incr}(\text{trie\_max})$ ;  $\text{trie\_taken}[\text{trie\_max}] \leftarrow \text{false}$ ;  $\text{trie\_link}(\text{trie\_max}) \leftarrow \text{trie\_max} + 1$ ;
     $\text{trie\_back}(\text{trie\_max}) \leftarrow \text{trie\_max} - 1$ ;
  until  $\text{trie\_max} = h + 256$ ;
  end

```

This code is used in section 964.

```

966. ⟨If all characters of the family fit relative to  $h$ , then goto found, otherwise goto not_found 966⟩ ≡
   $q \leftarrow \text{trie}_r[p]$ ;
  while  $q > 0$  do
    begin if  $\text{trie\_link}(h + \text{so}(\text{trie}_c[q])) = 0$  then goto not_found;
     $q \leftarrow \text{trie}_r[q]$ ;
  end;
  goto found

```

This code is used in section 964.

**967.**  $\langle$  Pack the family into *trie* relative to *h* 967  $\rangle \equiv$   
*trie\_taken*[*h*]  $\leftarrow$  *true*; *trie\_ref*[*p*]  $\leftarrow$  *h*; *q*  $\leftarrow$  *p*;  
**repeat** *z*  $\leftarrow$  *h* + *so*(*trie\_c*[*q*]); *l*  $\leftarrow$  *trie\_back*(*z*); *r*  $\leftarrow$  *trie\_link*(*z*); *trie\_back*(*r*)  $\leftarrow$  *l*; *trie\_link*(*l*)  $\leftarrow$  *r*;  
*trie\_link*(*z*)  $\leftarrow$  0;  
**if** *l* < 256 **then**  
  **begin if** *z* < 256 **then** *ll*  $\leftarrow$  *z* **else** *ll*  $\leftarrow$  256;  
  **repeat** *trie\_min*[*l*]  $\leftarrow$  *r*; *incr*(*l*);  
  **until** *l* = *ll*;  
  **end**;  
  *q*  $\leftarrow$  *trie\_r*[*q*];  
**until** *q* = 0

This code is used in section 964.

**968.** To pack the entire linked trie, we use the following recursive procedure.

$\langle$  Declare procedures for preprocessing hyphenation patterns 955  $\rangle + \equiv$   
**procedure** *trie\_pack*(*p* : *trie\_pointer*); { pack subtrees of a family }  
  **var** *q*: *trie\_pointer*; { a local variable that need not be saved on recursive calls }  
  **begin repeat** *q*  $\leftarrow$  *trie\_l*[*p*];  
  **if** (*q* > 0)  $\wedge$  (*trie\_ref*[*q*] = 0) **then**  
    **begin** *first\_fit*(*q*); *trie\_pack*(*q*);  
    **end**;  
  *p*  $\leftarrow$  *trie\_r*[*p*];  
**until** *p* = 0;  
**end**;

**969.** When the whole trie has been allocated into the sequential table, we must go through it once again so that *trie* contains the correct information. Null pointers in the linked trie will be represented by the value 0, which properly implements an “empty” family.

**define** *clear\_trie*  $\equiv$  { clear *trie*[*r*] }  
  **begin** *trie\_link*(*r*)  $\leftarrow$  0; *trie\_op*(*r*)  $\leftarrow$  *min\_trie\_op*; *trie\_char*(*r*)  $\leftarrow$  *min\_quarterword*;  
  { *trie\_char*  $\leftarrow$  *qi*(0) }  
  **end**

$\langle$  Move the data into *trie* 969  $\rangle \equiv$   
**if** *trie\_root* = 0 **then** { no patterns were given }  
  **begin for** *r*  $\leftarrow$  0 **to** 256 **do** *clear\_trie*;  
  *trie\_max*  $\leftarrow$  256;  
  **end**  
**else begin** *trie\_fix*(*trie\_root*); { this fixes the non-holes in *trie* }  
  *r*  $\leftarrow$  0; { now we will zero out all the holes }  
  **repeat** *s*  $\leftarrow$  *trie\_link*(*r*); *clear\_trie*; *r*  $\leftarrow$  *s*;  
  **until** *r* > *trie\_max*;  
  **end**;  
  *trie\_char*(0)  $\leftarrow$  *qi*("?"); { make *trie\_char*(*c*)  $\neq$  *c* for all *c* }

This code is used in section 977.

**970.** The fixing-up procedure is, of course, recursive. Since the linked trie usually has overlapping subtries, the same data may be moved several times; but that causes no harm, and at most as much work is done as it took to build the uncompressed trie.

```

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +≡
procedure trie_fix(p : trie_pointer); { moves p and its siblings into trie }
  var q : trie_pointer; { a local variable that need not be saved on recursive calls }
      c : ASCII_code; { another one that need not be saved }
      z : trie_pointer; { trie reference; this local variable must be saved }
  begin z ← trie_ref[p];
  repeat q ← trie_l[p]; c ← so(trie_c[p]); trie_link(z + c) ← trie_ref[q]; trie_char(z + c) ← qi(c);
      trie_op(z + c) ← trie_o[p];
      if q > 0 then trie_fix(q);
      p ← trie_r[p];
  until p = 0;
end;

```

**971.** Now let's go back to the easier problem, of building the linked trie. When INITEX has scanned the '\patterns' control sequence, it calls on *new\_patterns* to do the right thing.

```

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +≡
procedure new_patterns; { initializes the hyphenation pattern data }
  label done, done1;
  var k, l : 0 .. 64; { indices into hc and hyf; not always in small_number range }
      digit_sensed : boolean; { should the next digit be treated as a letter? }
      v : trie_opcode; { trie op code }
      p, q : trie_pointer; { nodes of trie traversed during insertion }
      first_child : boolean; { is p = trie_l[q]? }
      c : ASCII_code; { character being inserted }
  begin if trie_not_ready then
      begin set_cur_lang; scan_left_brace; { a left brace must follow \patterns }
      ⟨Enter all of the patterns into a linked trie, until coming to a right brace 972⟩;
      end
  else begin print_err("Too_late_for_"); print_esc("patterns");
      help1("All_patterns_must_be_given_before_typesetting_begins."); error;
      link(garbage) ← scan_toks(false, false); flush_list(def_ref);
      end;
  end;

```

**972.** Novices are not supposed to be using `\patterns`, so the error messages are terse. (Note that all error messages appear in T<sub>E</sub>X's string pool, even if they are used only by INITEX.)

⟨Enter all of the patterns into a linked trie, until coming to a right brace 972⟩ ≡

```

k ← 0; hyf[0] ← 0; digit_sensed ← false;
loop begin get_x_token;
  case cur_cmd of
    letter, other_char: ⟨Append a new letter or a hyphen level 973⟩;
    spacer, right_brace: begin if k > 0 then ⟨Insert a new pattern into the linked trie 974⟩;
      if cur_cmd = right_brace then goto done;
      k ← 0; hyf[0] ← 0; digit_sensed ← false;
      end;
    othercases begin print_err("Bad_"); print_esc("patterns"); help1("(See_□Appendix_□H.)"); error;
    end
  endcases;
end;

```

done:

This code is used in section 971.

**973.** ⟨Append a new letter or a hyphen level 973⟩ ≡

```

if digit_sensed ∨ (cur_chr < "0") ∨ (cur_chr > "9") then
  begin if cur_chr = "." then cur_chr ← 0 {edge-of-word delimiter}
  else begin cur_chr ← lc_code(cur_chr);
    if cur_chr = 0 then
      begin print_err("Nonletter"); help1("(See_□Appendix_□H.)"); error;
      end;
    end;
  if k < 63 then
    begin incr(k); hc[k] ← cur_chr; hyf[k] ← 0; digit_sensed ← false;
    end;
  end
else if k < 63 then
  begin hyf[k] ← cur_chr - "0"; digit_sensed ← true;
  end

```

This code is used in section 972.

**974.** When the following code comes into play, the pattern  $p_1 \dots p_k$  appears in  $hc[1 \dots k]$ , and the corresponding sequence of numbers  $n_0 \dots n_k$  appears in  $hyf[0 \dots k]$ .

```

⟨Insert a new pattern into the linked trie 974⟩ ≡
  begin ⟨Compute the trie op code, v, and set l ← 0 976⟩;
  q ← 0; hc[0] ← cur_lang;
  while l ≤ k do
    begin c ← hc[l]; incr(l); p ← trie_l[q]; first_child ← true;
    while (p > 0) ∧ (c > so(trie_c[p])) do
      begin q ← p; p ← trie_r[q]; first_child ← false;
      end;
    if (p = 0) ∨ (c < so(trie_c[p])) then
      ⟨Insert a new trie node between q and p, and make p point to it 975⟩;
      q ← p; { now node q represents p1 ... pl-1 }
      end;
    if trie_o[q] ≠ min_trie_op then
      begin print_err("Duplicate_pattern"); help1("(See Appendix H.)"); error;
      end;
    trie_o[q] ← v;
  end

```

This code is used in section 972.

```

975. ⟨Insert a new trie node between q and p, and make p point to it 975⟩ ≡
  begin if trie_ptr = trie_size then overflow("pattern_memory", trie_size);
  incr(trie_ptr); trie_r[trie_ptr] ← p; p ← trie_ptr; trie_l[p] ← 0;
  if first_child then trie_l[q] ← p else trie_r[q] ← p;
  trie_c[p] ← si(c); trie_o[p] ← min_trie_op;
  end

```

This code is used in section 974.

```

976. ⟨Compute the trie op code, v, and set l ← 0 976⟩ ≡
  if hc[1] = 0 then hyf[0] ← 0;
  if hc[k] = 0 then hyf[k] ← 0;
  l ← k; v ← min_trie_op;
  loop begin if hyf[l] ≠ 0 then v ← new_trie_op(k - l, hyf[l], v);
  if l > 0 then decr(l) else goto done1;
  end;
done1:

```

This code is used in section 974.

**977.** Finally we put everything together: Here is how the trie gets to its final, efficient form. The following packing routine is rigged so that the root of the linked tree gets mapped into location 1 of *trie*, as required by the hyphenation algorithm. This happens because the first call of *first\_fit* will “take” location 1.

⟨Declare procedures for preprocessing hyphenation patterns 955⟩ +=

**procedure** *init\_trie*;

**var** *p*: *trie\_pointer*; { pointer for initialization }

*j, k, t*: *integer*; { all-purpose registers for initialization }

*r, s*: *trie\_pointer*; { used to clean up the packed *trie* }

**begin** ⟨Get ready to compress the trie 963⟩;

**if** *trie\_root* ≠ 0 **then**

**begin** *first\_fit*(*trie\_root*); *trie\_pack*(*trie\_root*);

**end**;

  ⟨Move the data into *trie* 969⟩;

*trie\_not\_ready* ← *false*;

**end**;

**978. Breaking vertical lists into pages.** The *vsplit* procedure, which implements TEX's `\vsplit` operation, is considerably simpler than *line.break* because it doesn't have to worry about hyphenation, and because its mission is to discover a single break instead of an optimum sequence of breakpoints. But before we get into the details of *vsplit*, we need to consider a few more basic things.

**979.** A subroutine called *prune\_page\_top* takes a pointer to a vlist and returns a pointer to a modified vlist in which all glue, kern, and penalty nodes have been deleted before the first box or rule node. However, the first box or rule is actually preceded by a newly created glue node designed so that the topmost baseline will be at distance *split\_top\_skip* from the top, whenever this is possible without backspacing.

In this routine and those that follow, we make use of the fact that a vertical list contains no character nodes, hence the *type* field exists for each node in the list.

```
function prune_page_top(p : pointer): pointer; { adjust top after page break }
  var prev_p: pointer; { lags one step behind p }
      q: pointer; { temporary variable for list manipulation }
  begin prev_p ← temp_head; link(temp_head) ← p;
  while p ≠ null do
    case type(p) of
      dir_node, hlist_node, vlist_node, rule_node: ⟨ Insert glue for split_top_skip and set p ← null 980 ⟩;
      whatsit_node, mark_node, ins_node: begin prev_p ← p; p ← link(prev_p);
        end;
      glue_node, kern_node, penalty_node: begin q ← p; p ← link(q); link(q) ← null; link(prev_p) ← p;
        flush_node_list(q);
        end;
      othercases confusion("pruning")
    endcases;
  prune_page_top ← link(temp_head);
end;
```

```
980. ⟨ Insert glue for split_top_skip and set p ← null 980 ⟩ ≡
  begin q ← new_skip_param(split_top_skip_code); link(prev_p) ← q; link(q) ← p;
    { now temp_ptr = glue_ptr(q) }
  if width(temp_ptr) > height(p) then width(temp_ptr) ← width(temp_ptr) − height(p)
  else width(temp_ptr) ← 0;
  p ← null;
  end
```

This code is used in section 979.

**981.** The next subroutine finds the best place to break a given vertical list so as to obtain a box of height  $h$ , with maximum depth  $d$ . A pointer to the beginning of the vertical list is given, and a pointer to the optimum breakpoint is returned. The list is effectively followed by a forced break, i.e., a penalty node with the *eject\_penalty*; if the best break occurs at this artificial node, the value *null* is returned.

An array of six *scaled* distances is used to keep track of the height from the beginning of the list to the current place, just as in *line\_break*. In fact, we use one of the same arrays, only changing its name to reflect its new significance.

```

define active_height  $\equiv$  active_width { new name for the six distance variables }
define cur_height  $\equiv$  active_height[1] { the natural height }
define set_height_zero(#)  $\equiv$  active_height[#]  $\leftarrow$  0 { initialize the height to zero }
define update_heights = 90 { go here to record glue in the active_height table }
function vert_break(p : pointer; h, d : scaled): pointer; { finds optimum page break }
label done, not_found, update_heights;
var prev_p: pointer; { if p is a glue node, type(prev_p) determines whether p is a legal breakpoint }
    q, r: pointer; { glue specifications }
    pi: integer; { penalty value }
    b: integer; { badness at a trial breakpoint }
    least_cost: integer; { the smallest badness plus penalties found so far }
    best_place: pointer; { the most recent break that leads to least_cost }
    prev_dp: scaled; { depth of previous box in the list }
    t: small_number; { type of the node following a kern }
begin prev_p  $\leftarrow$  p; { an initial glue node is not a legal breakpoint }
    least_cost  $\leftarrow$  awful_bad; do_all_six(set_height_zero); prev_dp  $\leftarrow$  0;
loop begin < If node p is a legal breakpoint, check if this break is the best known, and goto done if p is
    null or if the page-so-far is already too full to accept more stuff 983 >;
    prev_p  $\leftarrow$  p; p  $\leftarrow$  link(prev_p);
end;
done: vert_break  $\leftarrow$  best_place;
end;

```

**982.** A global variable *best\_height\_plus\_depth* will be set to the natural size of the box that corresponds to the optimum breakpoint found by *vert\_break*. (This value is used by the insertion-splitting algorithm of the page builder.)

< Global variables 13 > + $\equiv$

*best\_height\_plus\_depth*: *scaled*; { height of the best box, without stretching or shrinking }

**983.** A subtle point to be noted here is that the maximum depth  $d$  might be negative, so *cur\_height* and *prev\_dp* might need to be corrected even after a glue or kern node.

```

⟨If node  $p$  is a legal breakpoint, check if this break is the best known, and goto done if  $p$  is null or if the
page-so-far is already too full to accept more stuff 983⟩ ≡

       `("Such_glue_doesn't_belong_there; but_you_can_safely_proceed,")`  
       `("since_the_offensive_shrinkability_has_been_made_finite.")`; *error*; *r* ← *new\_spec*(*q*);  
       *shrink\_order*(*r*) ← *normal*; *delete\_glue\_ref*(*q*); *glue\_ptr*(*p*) ← *r*; *q* ← *r*;  
     **end**;  
   **end**;  
   *cur\_height* ← *cur\_height* + *prev\_dp* + *width*(*q*); *prev\_dp* ← 0

This code is used in section 983.

**988.** Now we are ready to consider *vsplit* itself. Most of its work is accomplished by the two subroutines that we have just considered.

Given the number of a vlist box  $n$ , and given a desired page height  $h$ , the *vsplit* function finds the best initial segment of the vlist and returns a box for a page of height  $h$ . The remainder of the vlist, if any, replaces the original box, after removing glue and penalties and adjusting for *split\_top\_skip*. Mark nodes in the split-off box are used to set the values of *split\_first\_mark* and *split\_bot\_mark*; we use the fact that *split\_first\_mark* = *null* if and only if *split\_bot\_mark* = *null*.

The original box becomes “void” if and only if it has been entirely extracted. The extracted box is “void” if and only if the original box was void (or if it was, erroneously, an hlist box).

```
function vsplit(n : eight_bits; h : scaled): pointer; { extracts a page of height h from box n }
  label exit, done;
  var v: pointer; { the box to be split }
      w: pointer; { dir_node }
      p: pointer; { runs through the vlist }
      q: pointer; { points to where the break occurs }
  begin v ← box(n);
  if split_first_mark ≠ null then
    begin delete_token_ref(split_first_mark); split_first_mark ← null; delete_token_ref(split_bot_mark);
    split_bot_mark ← null;
    end;
  ⟨Dispense with trivial cases of void or bad boxes 989⟩;
  q ← vert_break(list_ptr(v), h, split_max_depth);
  ⟨Look at all the marks in nodes before the break, and set the final link to null at the break 990⟩;
  q ← prune_page_top(q); p ← list_ptr(v);
  if q = null then box(n) ← null { the eq_level of the box stays the same }
  else begin box(n) ← vpack(q, natural); set_box_dir(box(n))(box_dir(v));
    end;
  q ← vpackage(p, h, exactly, split_max_depth); set_box_dir(q)(box_dir(v)); delete_glue_ref(space_ptr(v));
  delete_glue_ref(xspace_ptr(v)); free_node(v, box_node_size); vsplit ← q;
  exit: end;
```

**989.** ⟨Dispense with trivial cases of void or bad boxes 989⟩ ≡

```
if v = null then
  begin vsplit ← null; return;
  end;
if type(v) = dir_node then
  begin w ← v; v ← list_ptr(v); delete_glue_ref(space_ptr(w)); delete_glue_ref(xspace_ptr(w));
  free_node(w, box_node_size);
  end;
if type(v) ≠ vlist_node then
  begin print_err(""); print_esc("vsplit"); print("_needs_a_"); print_esc("vbox");
  help2("The_box_you_are_trying_to_split_is_an_hbox.")
  ("I_can't_split_such_a_box,_so_I'll_leave_it_alone."); error; vsplit ← null; return;
  end;
  flush_node_list(link(v)); link(v) ← null
```

This code is used in section 988.

**990.** It's possible that the box begins with a penalty node that is the “best” break, so we must be careful to handle this special case correctly.

(Look at all the marks in nodes before the break, and set the final link to *null* at the break 990) ≡

```

p ← list_ptr(v);

if p = q then list_ptr(v) ← null
else loop begin if type(p) = mark_node then
  if split_first_mark = null then
    begin split_first_mark ← mark_ptr(p); split_bot_mark ← split_first_mark;
    token_ref_count(split_first_mark) ← token_ref_count(split_first_mark) + 2;
    end
  else begin delete_token_ref(split_bot_mark); split_bot_mark ← mark_ptr(p);
  add_token_ref(split_bot_mark);
  end;
if link(p) = q then
  begin link(p) ← null; goto done;
  end;
  p ← link(p);
end;
```

*done*:

This code is used in section 988.

**991. The page builder.** When T<sub>E</sub>X appends new material to its main vlist in vertical mode, it uses a method something like *vsplit* to decide where a page ends, except that the calculations are done “on line” as new items come in. The main complication in this process is that insertions must be put into their boxes and removed from the vlist, in a more-or-less optimum manner.

We shall use the term “current page” for that part of the main vlist that is being considered as a candidate for being broken off and sent to the user’s output routine. The current page starts at *link(page\_head)*, and it ends at *page\_tail*. We have *page\_head = page\_tail* if this list is empty.

Utter chaos would reign if the user kept changing page specifications while a page is being constructed, so the page builder keeps the pertinent specifications frozen as soon as the page receives its first box or insertion. The global variable *page\_contents* is *empty* when the current page contains only mark nodes and content-less whatsit nodes; it is *inserts\_only* if the page contains only insertion nodes in addition to marks and whatsits. Glue nodes, kern nodes, and penalty nodes are discarded until a box or rule node appears, at which time *page\_contents* changes to *box\_there*. As soon as *page\_contents* becomes non-*empty*, the current *vsize* and *max\_depth* are squirreled away into *page\_goal* and *page\_max\_depth*; the latter values will be used until the page has been forwarded to the user’s output routine. The  $\backslash\text{topskip}$  adjustment is made when *page\_contents* changes to *box\_there*.

Although *page\_goal* starts out equal to *vsize*, it is decreased by the scaled natural height-plus-depth of the insertions considered so far, and by the  $\backslash\text{skip}$  corrections for those insertions. Therefore it represents the size into which the non-inserted material should fit, assuming that all insertions in the current page have been made.

The global variables *best\_page\_break* and *least\_page\_cost* correspond respectively to the local variables *best\_place* and *least\_cost* in the *vert\_break* routine that we have already studied; i.e., they record the location and value of the best place currently known for breaking the current page. The value of *page\_goal* at the time of the best break is stored in *best\_size*.

```
define inserts_only = 1 { page_contents when an insert node has been contributed, but no boxes }
define box_there = 2 { page_contents when a box or rule has been contributed }
```

⟨ Global variables 13 ⟩ +≡

```
page_tail: pointer; { the final node on the current page }
page_contents: empty .. box_there; { what is on the current page so far? }
page_max_depth: scaled; { maximum box depth on page being built }
best_page_break: pointer; { break here to get the best page known so far }
least_page_cost: integer; { the score for this currently best page }
best_size: scaled; { its page_goal }
```

**992.** The page builder has another data structure to keep track of insertions. This is a list of four-word nodes, starting and ending at *page\_ins.head*. That is, the first element of the list is node  $r_1 = \text{link}(\text{page\_ins\_head})$ ; node  $r_j$  is followed by  $r_{j+1} = \text{link}(r_j)$ ; and if there are  $n$  items we have  $r_{n+1} = \text{page\_ins\_head}$ . The *subtype* field of each node in this list refers to an insertion number; for example, ‘\insert 250’ would correspond to a node whose *subtype* is *qi*(250) (the same as the *subtype* field of the relevant *ins\_node*). These *subtype* fields are in increasing order, and *subtype*(*page\_ins.head*) = *qi*(255), so *page\_ins.head* serves as a convenient sentinel at the end of the list. A record is present for each insertion number that appears in the current page.

The *type* field in these nodes distinguishes two possibilities that might occur as we look ahead before deciding on the optimum page break. If *type*( $r$ ) = *inserting*, then *height*( $r$ ) contains the total of the height-plus-depth dimensions of the box and all its inserts seen so far. If *type*( $r$ ) = *split\_up*, then no more insertions will be made into this box, because at least one previous insertion was too big to fit on the current page; *broken\_ptr*( $r$ ) points to the node where that insertion will be split, if T<sub>E</sub>X decides to split it, *broken\_ins*( $r$ ) points to the insertion node that was tentatively split, and *height*( $r$ ) includes also the natural height plus depth of the part that would be split off.

In both cases, *last\_ins\_ptr*( $r$ ) points to the last *ins\_node* encountered for box *qo*(*subtype*( $r$ )) that would be at least partially inserted on the next page; and *best\_ins\_ptr*( $r$ ) points to the last such *ins\_node* that should actually be inserted, to get the page with minimum badness among all page breaks considered so far. We have *best\_ins\_ptr*( $r$ ) = *null* if and only if no insertion for this box should be made to produce this optimum page.

The data structure definitions here use the fact that the *height* field appears in the fourth word of a box node.

```

define page_ins_node_size = 4 { number of words for a page insertion node }
define inserting = 0 { an insertion class that has not yet overflowed }
define split_up = 1 { an overflowed insertion class }
define broken_ptr(#) ≡ link(# + 1) { an insertion for this class will break here if anywhere }
define broken_ins(#) ≡ info(# + 1) { this insertion might break at broken_ptr }
define last_ins_ptr(#) ≡ link(# + 2) { the most recent insertion for this subtype }
define best_ins_ptr(#) ≡ info(# + 2) { the optimum most recent insertion }

```

```

⟨ Initialize the special list heads and constant nodes 801 ⟩ +≡
  subtype(page_ins.head) ← qi(255); type(page_ins.head) ← split_up; link(page_ins.head) ← page_ins.head;

```

**993.** An array *page\_so\_far* records the heights and depths of everything on the current page. This array contains six *scaled* numbers, like the similar arrays already considered in *line\_break* and *vert\_break*; and it also contains *page\_goal* and *page\_depth*, since these values are all accessible to the user via *set\_page\_dimen* commands. The value of *page\_so\_far*[1] is also called *page\_total*. The stretch and shrink components of the `\skip` corrections for each insertion are included in *page\_so\_far*, but the natural space components of these corrections are not, since they have been subtracted from *page\_goal*.

The variable *page\_depth* records the depth of the current page; it has been adjusted so that it is at most *page\_max\_depth*. The variable *last\_glue* points to the glue specification of the most recent node contributed from the contribution list, if this was a glue node; otherwise *last\_glue* = *max\_halfword*. (If the contribution list is nonempty, however, the value of *last\_glue* is not necessarily accurate.) The variables *last\_penalty* and *last\_kern* are similar. And finally, *insert\_penalties* holds the sum of the penalties associated with all split and floating insertions.

```

define page_goal ≡ page_so_far[0] { desired height of information on page being built }
define page_total ≡ page_so_far[1] { height of the current page }
define page_shrink ≡ page_so_far[6] { shrinkability of the current page }
define page_depth ≡ page_so_far[7] { depth of the current page }

```

⟨ Global variables 13 ⟩ +=

```

page_so_far: array [0 .. 7] of scaled; { height and glue of the current page }
last_glue: pointer; { used to implement \lastskip }
last_penalty: integer; { used to implement \lastpenalty }
last_kern: scaled; { used to implement \lastkern }
insert_penalties: integer; { sum of the penalties for held-over insertions }

```

This code is used in section 224.

**998.** Here is a procedure that is called when the *page\_contents* is changing from *empty* to *inserts\_only* or *box\_there*.

```

      define set_page_so_far_zero(#) ≡ page_so_far[#] ← 0
procedure freeze_page_specs(s : small_number);
  begin page_contents ← s; page_goal ← vsize; page_max_depth ← max_depth; page_depth ← 0;
  do_all_six(set_page_so_far_zero); least_page_cost ← awful_bad;
  stat if tracing_pages > 0 then
    begin begin_diagnostic; print_nl("%_goal_height="); print_scaled(page_goal);
    print(",_max_depth="); print_scaled(page_max_depth); end_diagnostic(false);
    end; tats
  end;

```

**999.** Pages are built by appending nodes to the current list in T<sub>E</sub>X's vertical mode, which is at the outermost level of the semantic nest. This vlist is split into two parts; the "current page" that we have been talking so much about already, and the "contribution list" that receives new nodes as they are created. The current page contains everything that the page builder has accounted for in its data structures, as described above, while the contribution list contains other things that have been generated by other parts of T<sub>E</sub>X but have not yet been seen by the page builder. The contribution list starts at *link(contrib\_head)*, and it ends at the current node in T<sub>E</sub>X's vertical mode.

When T<sub>E</sub>X has appended new material in vertical mode, it calls the procedure *build\_page*, which tries to catch up by moving nodes from the contribution list to the current page. This procedure will succeed in its goal of emptying the contribution list, unless a page break is discovered, i.e., unless the current page has grown to the point where the optimum next page break has been determined. In the latter case, the nodes after the optimum break will go back onto the contribution list, and control will effectively pass to the user's output routine.

We make *type(page\_head) = glue\_node*, so that an initial glue node on the current page will not be considered a valid breakpoint.

```
⟨Initialize the special list heads and constant nodes 801⟩ +≡
  type(page_head) ← glue_node; subtype(page_head) ← normal;
```

**1000.** The global variable *output\_active* is true during the time the user's output routine is driving T<sub>E</sub>X.

```
⟨Global variables 13⟩ +≡
output_active: boolean; { are we in the midst of an output routine? }
```

**1001.** ⟨Set initial values of key variables 21⟩ +≡

```
output_active ← false; insert_penalties ← 0;
```

**1002.** The page builder is ready to start a fresh page if we initialize the following state variables. (However, the page insertion list is initialized elsewhere.)

```
⟨Start a new current page 1002⟩ ≡
  page_contents ← empty; page_tail ← page_head; link(page_head) ← null;
  last_glue ← max_halfword; last_penalty ← 0; last_kern ← 0; page_depth ← 0; page_max_depth ← 0
```

This code is used in section 1028.

**1003.** At certain times box 255 is supposed to be void (i.e., *null*), or an insertion box is supposed to be ready to accept a vertical list. If not, an error message is printed, and the following subroutine flushes the unwanted contents, reporting them to the user.

```
procedure box_error(n : eight_bits);
  begin error; begin_diagnostic; print_nl("The following box has been deleted:");
  show_box(box(n)); end_diagnostic(true); flush_node_list(box(n)); box(n) ← null;
end;
```

**1004.** The following procedure guarantees that a given box register does not contain an `\hbox`.

```

procedure ensure_vbox(n : eight_bits);
  var p: pointer; { the box register contents }
  begin p ← box(n);
  if p ≠ null then
    if type(p) = dir_node then
      begin p ← list_ptr(p); delete_glue_ref(space_ptr(box(n))); delete_glue_ref(xspace_ptr(box(n)));
      free_node(box(n), box_node_size); box(n) ← p
      end;
    if p ≠ null then
      if type(p) ≠ vlist_node then
        begin print_err("Insertions can only be added to a vbox");
        help3("Tut_tut: You're trying to insert into a")
        (" \box register that now contains an \hbox.")
        ("Proceed, and I'll discard its present contents."); box_error(n);
        end;
      end;
    end;

```

**1005.** T<sub>E</sub>X is not always in vertical mode at the time *build\_page* is called; the current mode reflects what T<sub>E</sub>X should return to, after the contribution list has been emptied. A call on *build\_page* should be immediately followed by `'goto big_switch'`, which is T<sub>E</sub>X's central control point.

```

define contribute = 80 { go here to link a node into the current page }

```

⟨ Declare the procedure called *fire\_up* 1023 ⟩

```

procedure build_page; { append contributions to the current page }
  label exit, done, done1, continue, contribute, update_heights;
  var p: pointer; { the node being appended }
      q, r: pointer; { nodes being examined }
      b, c: integer; { badness and cost of current page }
      pi: integer; { penalty to be added to the badness }
      n: min_quarterword .. 255; { insertion box number }
      delta, h, w: scaled; { sizes used for insertion calculations }
  begin if (link(contrib_head) = null) ∨ output_active then return;
  repeat continue: p ← link(contrib_head);
    ⟨ Update the values of last_glue, last_penalty, and last_kern 1007 ⟩;
    ⟨ Move node p to the current page; if it is time for a page break, put the nodes following the break
      back onto the contribution list, and return to the user's output routine if there is one 1008 ⟩;
  until link(contrib_head) = null;
  ⟨ Make the contribution list empty by setting its tail to contrib_head 1006 ⟩;
exit: end;

```

**1006.** **define** *contrib\_tail* ≡ *nest*[0].*tail\_field* { tail of the contribution list }

⟨ Make the contribution list empty by setting its tail to *contrib\_head* 1006 ⟩ ≡

```

  if nest_ptr = 0 then tail ← contrib_head { vertical mode }
  else contrib_tail ← contrib_head { other modes }

```

This code is used in section 1005.

```

1007.  ⟨Update the values of last_glue, last_penalty, and last_kern 1007⟩ ≡
  if last_glue ≠ max_halfword then delete_glue_ref(last_glue);
  last_penalty ← 0; last_kern ← 0;
  if type(p) = glue_node then
    begin last_glue ← glue_ptr(p); add_glue_ref(last_glue);
    end
  else begin last_glue ← max_halfword;
    if type(p) = penalty_node then last_penalty ← penalty(p)
    else if type(p) = kern_node then last_kern ← width(p);
    end

```

This code is used in section 1005.

**1008.** The code here is an example of a many-way switch into routines that merge together in different places. Some people call this unstructured programming, but the author doesn't see much wrong with it, as long as the various labels have a well-understood meaning.

```

⟨Move node p to the current page; if it is time for a page break, put the nodes following the break back
  onto the contribution list, and return to the user's output routine if there is one 1008⟩ ≡
  ⟨If the current page is empty and node p is to be deleted, goto done1; otherwise use node p to update
    the state of the current page; if this node is an insertion, goto contribute; otherwise if this node is
    not a legal breakpoint, goto contribute or update_heights; otherwise set pi to the penalty associated
    with this breakpoint 1011⟩;
  ⟨Check if node p is a new champion breakpoint; then if it is time for a page break, prepare for output,
    and either fire up the user's output routine and return or ship out the page and goto done 1016⟩;

  ("must have finite shrinkability. But you may proceed,")
  ("since the offensive shrinkability has been made finite."); error;
  end;
end

```

This code is used in section 1019.

**1021.** Here is the code that will split a long footnote between pages, in an emergency. The current situation deserves to be recapitulated: Node  $p$  is an insertion into box  $n$ ; the insertion will not fit, in its entirety, either because it would make the total contents of box  $n$  greater than  $\backslash\text{dimen } n$ , or because it would make the incremental amount of growth  $h$  greater than the available space  $\textit{delta}$ , or both. (This amount  $h$  has been weighted by the insertion scaling factor, i.e., by  $\backslash\text{count } n$  over 1000.) Now we will choose the best way to break the vlist of the insertion, using the same criteria as in the  $\backslash\text{vsplit}$  operation.

```

⟨Find the best way to split the insertion, and change  $\textit{type}(r)$  to  $\textit{split\_up}$  1021⟩ ≡
begin if  $\textit{count}(n) \leq 0$  then  $w \leftarrow \textit{max\_dimen}$

 $\textit{end\_diagnostic}(\textit{false})$ ;
end

```

This code is used in section 1021.

**1023.** When the page builder has looked at as much material as could appear before the next page break, it makes its decision. The break that gave minimum badness will be used to put a completed “page” into box 255, with insertions appended to their other boxes.

We also set the values of *top\_mark*, *first\_mark*, and *bot\_mark*. The program uses the fact that *bot\_mark*  $\neq$  *null* implies *first\_mark*  $\neq$  *null*; it also knows that *bot\_mark* = *null* implies *top\_mark* = *first\_mark* = *null*.

The *fire\_up* subroutine prepares to output the current page at the best place; then it fires up the user’s output routine, if there is one, or it simply ships out the page. There is one parameter, *c*, which represents the node that was being contributed to the page when the decision to force an output was made.

⟨Declare the procedure called *fire\_up* 1023⟩ ≡

**procedure** *fire\_up*(*c* : *pointer*);

**label** *exit*;

**var** *p, q, r, s*: *pointer*; { nodes being examined and/or changed }

*prev\_p*: *pointer*; { predecessor of *p* }

*n*: *min\_quarterword* .. 255; { insertion box number }

*wait*: *boolean*; { should the present insertion be held over? }

*save\_vbadness*: *integer*; { saved value of *vbadness* }

*save\_vfuzz*: *scaled*; { saved value of *vfuzz* }

*save\_split\_top\_skip*: *pointer*; { saved value of *split\_top\_skip* }

**begin** ⟨Set the value of *output\_penalty* 1024⟩;

**if** *bot\_mark*  $\neq$  *null* **then**

**begin** **if** *top\_mark*  $\neq$  *null* **then** *delete\_token\_ref*(*top\_mark*);

*top\_mark*  $\leftarrow$  *bot\_mark*; *add\_token\_ref*(*top\_mark*); *delete\_token\_ref*(*first\_mark*); *first\_mark*  $\leftarrow$  *null*;

**end**;

  ⟨Put the optimal current page into box 255, update *first\_mark* and *bot\_mark*, append insertions to their boxes, and put the remaining nodes back on the contribution list 1025⟩;

**if** (*top\_mark*  $\neq$  *null*)  $\wedge$  (*first\_mark* = *null*) **then**

**begin** *first\_mark*  $\leftarrow$  *top\_mark*; *add\_token\_ref*(*top\_mark*);

**end**;

**if** *output\_routine*  $\neq$  *null* **then**

**if** *dead\_cycles*  $\geq$  *max\_dead\_cycles* **then**

      ⟨Explain that too many dead cycles have occurred in a row 1035⟩

**else** ⟨Fire up the user’s output routine and **return** 1036⟩;

  ⟨Perform the default output routine 1034⟩;

*exit*: **end**;

This code is used in section 1005.

**1024.** ⟨Set the value of *output\_penalty* 1024⟩ ≡

**if** *type*(*best\_page\_break*) = *penalty\_node* **then**

**begin** *geq\_word\_define*(*int\_base* + *output\_penalty\_code*, *penalty*(*best\_page\_break*));

*penalty*(*best\_page\_break*)  $\leftarrow$  *inf\_penalty*;

**end**

**else** *geq\_word\_define*(*int\_base* + *output\_penalty\_code*, *inf\_penalty*)

This code is used in section 1023.

**1025.** As the page is finally being prepared for output, pointer  $p$  runs through the vlist, with  $prev\_p$  trailing behind; pointer  $q$  is the tail of a list of insertions that are being held over for a subsequent page.

```

⟨Put the optimal current page into box 255, update first\_mark and bot\_mark, append insertions to their
boxes, and put the remaining nodes back on the contribution list 1025⟩ ≡

end

```

This code is used in section 1025.

**1028.** When the following code is executed, the current page runs from node  $link(page\_head)$  to node  $prev\_p$ , and the nodes from  $p$  to  $page\_tail$  are to be placed back at the front of the contribution list. Furthermore the heldover insertions appear in a list from  $link(hold\_head)$  to  $q$ ; we will put them into the current page list for safekeeping while the user's output routine is active. We might have  $q = hold\_head$ ; and  $p = null$  if and only if  $prev\_p = page\_tail$ . Error messages are suppressed within  $vpackage$ , since the box might appear to be overfull or underfull simply because the stretch and shrink from the  $\backslashskip$  registers for inserts are not actually present in the box.

```

⟨Break the current page at node  $p$ , put it in box 255, and put the remaining nodes on the contribution
list 1028⟩ ≡
if  $p \neq null$  then
  begin if  $link(contrib\_head) = null$  then
    if  $nest\_ptr = 0$  then  $tail \leftarrow page\_tail$ 
    else  $contrib\_tail \leftarrow page\_tail$ ;
     $link(page\_tail) \leftarrow link(contrib\_head)$ ;  $link(contrib\_head) \leftarrow p$ ;  $link(prev\_p) \leftarrow null$ ;
  end;
   $save\_vbadness \leftarrow vbadness$ ;  $vbadness \leftarrow inf\_bad$ ;  $save\_vfuzz \leftarrow vfuzz$ ;  $vfuzz \leftarrow max\_dimen$ ;
  { inhibit error messages }
   $box(255) \leftarrow vpackage(link(page\_head), best\_size, exactly, page\_max\_depth)$ ;
   $set\_box\_dir(box(255))(page\_dir)$ ;  $vbadness \leftarrow save\_vbadness$ ;  $vfuzz \leftarrow save\_vfuzz$ ;
  if  $last\_glue \neq max\_halfword$  then  $delete\_glue\_ref(last\_glue)$ ;
  ⟨Start a new current page 1002⟩; { this sets  $last\_glue \leftarrow max\_halfword$  }
  if  $q \neq hold\_head$  then
    begin  $link(page\_head) \leftarrow link(hold\_head)$ ;  $page\_tail \leftarrow q$ ;
    end

```

This code is used in section 1025.

**1029.** If many insertions are supposed to go into the same box, we want to know the position of the last node in that box, so that we don't need to waste time when linking further information into it. The  $last\_ins\_ptr$  fields of the page insertion nodes are therefore used for this purpose during the packaging phase.

```

⟨Prepare all the boxes involved in insertions to act as queues 1029⟩ ≡
  begin  $r \leftarrow link(page\_ins\_head)$ ;
  while  $r \neq page\_ins\_head$  do
    begin if  $best\_ins\_ptr(r) \neq null$  then
      begin  $n \leftarrow go(subtype(r))$ ;  $ensure\_vbox(n)$ ;
      if  $box(n) = null$  then  $box(n) \leftarrow new\_null\_box$ ;
       $p \leftarrow box(n) + list\_offset$ ;
      while  $link(p) \neq null$  do  $p \leftarrow link(p)$ ;
       $last\_ins\_ptr(r) \leftarrow p$ ;
    end;
     $r \leftarrow link(r)$ ;
  end;
end

```

This code is used in section 1025.

```

1030. ⟨Delete the page-insertion nodes 1030⟩ ≡
   $r \leftarrow link(page\_ins\_head)$ ;
  while  $r \neq page\_ins\_head$  do
    begin  $q \leftarrow link(r)$ ;  $free\_node(r, page\_ins\_node\_size)$ ;  $r \leftarrow q$ ;
    end;
   $link(page\_ins\_head) \leftarrow page\_ins\_head$ 

```

This code is used in section 1025.

**1031.** We will set  $best\_ins\_ptr \leftarrow null$  and package the box corresponding to insertion node  $r$ , just after making the final insertion into that box. If this final insertion is ‘*split\_up*’, the remainder after splitting and pruning (if any) will be carried over to the next page.

```

⟨Either insert the material specified by node  $p$  into the appropriate box, or hold it for the next page; also
  delete node  $p$  from the current page 1031⟩ ≡
begin  $r \leftarrow link(page\_ins\_head)$ ;
while  $subtype(r) \neq subtype(p)$  do  $r \leftarrow link(r)$ ;

    end

```

This code is used in section 1037.

**1040. The chief executive.** We come now to the *main\_control* routine, which contains the master switch that causes all the various pieces of T<sub>E</sub>X to do their things, in the right order.

In a sense, this is the grand climax of the program: It applies all the tools that we have worked so hard to construct. In another sense, this is the messiest part of the program: It necessarily refers to other pieces of code all over the place, so that a person can't fully understand what is going on without paging back and forth to be reminded of conventions that are defined elsewhere. We are now at the hub of the web, the central nervous system that touches most of the other parts and ties them together.

The structure of *main\_control* itself is quite simple. There's a label called *big\_switch*, at which point the next token of input is fetched using *get\_x\_token*. Then the program branches at high speed into one of about 100 possible directions, based on the value of the current mode and the newly fetched command code; the sum  $abs(mode) + cur\_cmd$  indicates what to do next. For example, the case '*vmode* + *letter*' arises when a letter occurs in vertical mode (or internal vertical mode); this case leads to instructions that initialize a new paragraph and enter horizontal mode.

The big **case** statement that contains this multiway switch has been labeled *reswitch*, so that the program can **goto** *reswitch* when the next token has already been fetched. Most of the cases are quite short; they call an "action procedure" that does the work for that case, and then they either **goto** *reswitch* or they "fall through" to the end of the **case** statement, which returns control back to *big\_switch*. Thus, *main\_control* is not an extremely large procedure, in spite of the multiplicity of things it must do; it is small enough to be handled by Pascal compilers that put severe restrictions on procedure size.

One case is singled out for special treatment, because it accounts for most of T<sub>E</sub>X's activities in typical applications. The process of reading simple text and converting it into *char\_node* records, while looking for ligatures and kerns, is part of T<sub>E</sub>X's "inner loop"; the whole program runs efficiently when its inner loop is fast, so this part has been written with particular care.

**1041.** We shall concentrate first on the inner loop of *main\_control*, deferring consideration of the other cases until later.

```

define big_switch = 60 { go here to branch on the next token of input }
define main_loop = 70 { go here to typeset a string of consecutive characters }
define main_loop_wrapup = 80 { go here to finish a character or ligature }
define main_loop_move = 90 { go here to advance the ligature cursor }
define main_loop_move_lig = 95 { same, when advancing past a generated ligature }
define main_loop_lookahead = 100 { go here to bring in another character, if any }
define main_lig_loop = 110 { go here to check for ligatures or kerning }
define append_normal_space = 120 { go here to append a normal space between words }
define main_loop_j = 130 { like main_loop, but cur_chr holds a KANJI code }
define skip_loop = 141
define again_2 = 150

    begin back_input; check_interrupt; goto big_switch;
    end;
  debug if panicking then check_mem(false); gubed
  if tracing_commands > 0 then show_cur_cmd_chr

```

This code is used in section 1041.

**1043.** The following part of the program was first written in a structured manner, according to the philosophy that “premature optimization is the root of all evil.” Then it was rearranged into pieces of spaghetti so that the most common actions could proceed with little or no redundancy.

The original unoptimized form of this algorithm resembles the *reconstitute* procedure, which was described earlier in connection with hyphenation. Again we have an implied “cursor” between characters *cur\_l* and *cur\_r*. The main difference is that the *lig\_stack* can now contain a charnode as well as pseudo-ligatures; that stack is now usually nonempty, because the next character of input (if any) has been appended to it. In *main\_control* we have

$$cur_r = \begin{cases} character(lig\_stack), & \text{if } lig\_stack > null; \\ font\_bchar[cur\_font], & \text{otherwise;} \end{cases}$$

except when  $character(lig\_stack) = font\_false\_bchar[cur\_font]$ . Several additional global variables are needed.

```

⟨ Global variables 13 ⟩ +≡
main_f: internal_font_number; { the current font }
main_i: four_quarters; { character information bytes for cur_l }
main_j: four_quarters; { ligature/kern command }
main_k: font_index; { index into font_info }
main_p: pointer; { temporary register for list manipulation }
main_s: integer; { space factor value }
bchar: halfword; { right boundary character of current font, or non_char }
false_bchar: halfword; { nonexistent character matching bchar, or non_char }
cancel_boundary: boolean; { should the left boundary be ignored? }
ins_disc: boolean; { should we insert a discretionary node? }

```

**1044.** The boolean variables of the main loop are normally false, and always reset to false before the loop is left. That saves us the extra work of initializing each time.

```

⟨ Set initial values of key variables 21 ⟩ +≡
  ligature_present ← false; cancel_boundary ← false; lft_hit ← false; rt_hit ← false; ins_disc ← false;

```

**1045.** We leave the *space\_factor* unchanged if *sf\_code*(*cur\_chr*) = 0; otherwise we set it equal to *sf\_code*(*cur\_chr*).■ except that it should never change from a value less than 1000 to a value exceeding 1000. The most common case is *sf\_code*(*cur\_chr*) = 1000, so we want that case to be fast.

The overall structure of the main loop is presented here. Some program labels are inside the individual sections.

```

define adjust_space_factor ≡
  main_s ← sf_code(cur_chr);
  if main_s = 1000 then space_factor ← 1000
  else if main_s < 1000 then
    begin if main_s > 0 then space_factor ← main_s;
    end
    else if space_factor < 1000 then space_factor ← 1000
    else space_factor ← main_s

```

  if lig_stack = null then goto main_loop_wrapup
  else goto main_loop_move + 1;
  end
endcases;
if op_byte(main_j) > qi(4) then
  if op_byte(main_j) ≠ qi(7) then goto main_loop_wrapup;
if cur_l < non_char then goto main_lig_loop;
main_k ← bchar_label[main_f]; goto main_lig_loop + 1;
end

```

This code is used in section 1051.

**1053.** The occurrence of blank spaces is almost part of T<sub>E</sub>X's inner loop, since we usually encounter about one space for every five non-blank characters. Therefore *main\_control* gives second-highest priority to ordinary spaces.

When a glue parameter like `\spaceskip` is set to 'Opt', we will see to it later that the corresponding glue specification is precisely *zero\_glue*, not merely a pointer to some specification that happens to be full of zeroes. Therefore it is simple to test whether a glue parameter is zero or not.

```

⟨ Append a normal inter-word space to the current list, then goto big_switch 1053 ⟩ ≡
if space_skip = zero_glue then
  begin ⟨ Find the glue specification, main_p, for text spaces in the current font 1054 ⟩;
  temp_ptr ← new_glue(main_p);
  end
else temp_ptr ← new_param_glue(space_skip_code);
if  $\neg$ is_char_node(tail) ∧ (type(tail) = disp_node) then
  begin link(prev_node) ← temp_ptr; link(temp_ptr) ← tail; prev_node ← temp_ptr;
  end
else begin link(tail) ← temp_ptr; tail ← temp_ptr;
  end;
goto big_switch

```

This code is used in section 1041.

**1054.** Having *font\_glue* allocated for each text font saves both time and memory. If any of the three spacing parameters are subsequently changed by the use of `\fontdimen`, the *find\_font\_dimen* procedure deallocates the *font\_glue* specification allocated here.

```

⟨ Find the glue specification, main_p, for text spaces in the current font 1054 ⟩ ≡
begin main_p ← font_glue[cur_font];
if main_p = null then
  begin main_p ← new_spec(zero_glue); main_k ← param_base[cur_font] + space_code;
  width(main_p) ← font_info[main_k].sc; { that's space(cur_font) }
  stretch(main_p) ← font_info[main_k + 1].sc; { and space_stretch(cur_font) }
  shrink(main_p) ← font_info[main_k + 2].sc; { and space_shrink(cur_font) }
  font_glue[cur_font] ← main_p;
  end;
end

```

This code is used in sections 1053 and 1055.

**1055.**  $\langle$  Declare action procedures for use by *main\_control* 1055  $\rangle \equiv$

   $\langle$  Cases of *main\_control* that are for extensions to T<sub>E</sub>X 1360  $\rangle$

This code is used in section 1041.

**1058.** Here is a list of cases where the user has probably gotten into or out of math mode by mistake. T<sub>E</sub>X will insert a dollar sign and rescan the current token.

```
define non_math(#) ≡ vmode + #, hmode + #
```

⟨Math-only cases in non-math modes, or vice versa 1058⟩ ≡

```
non_math(sup_mark), non_math(sub_mark), non_math(math_char_num), non_math(math_given),
non_math(math_comp), non_math(delim_num), non_math(left_right), non_math(above),
non_math(radical), non_math(math_style), non_math(math_choice), non_math(vcenter),
non_math(non_script), non_math(mkern), non_math(limit_switch), non_math(mskip),
non_math(math_accent), mmode + endv, mmode + par_end, mmode + stop, mmode + vskip,
mmode + un_vbox, mmode + valign, mmode + hrule
```

This code is used in section 1057.

**1059.** ⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```
procedure insert_dollar_sign;
```

```
begin back_input; cur_tok ← math_shift_token + "$"; print_err("Missing_$_inserted");
help2("I've_just_inserted_a_begin-math/end-math_symbol_since_I_think")
("you_left_one_out.Proceed_with_fingers_crossed."); ins_error;
end;
```

**1060.** When erroneous situations arise, T<sub>E</sub>X usually issues an error message specific to the particular error. For example, ‘\noalign’ should not appear in any mode, since it is recognized by the *align\_peek* routine in all of its legitimate appearances; a special error message is given when ‘\noalign’ occurs elsewhere. But sometimes the most appropriate error message is simply that the user is not allowed to do what he or she has attempted. For example, ‘\moveleft’ is allowed only in vertical mode, and ‘\lower’ only in non-vertical modes. Such cases are enumerated here and in the other sections referred to under ‘See also . . .’

⟨Forbidden cases detected in *main\_control* 1060⟩ ≡

```
vmode + vmove, hmode + hmove, mmode + hmove, any_mode(last_item),
```

See also sections 1110, 1123, and 1156.

This code is used in section 1057.

**1061.** The ‘*you\_cant*’ procedure prints a line saying that the current command is illegal in the current mode; it identifies these things symbolically.

⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```
procedure you_cant;
```

```
begin print_err("You_cant_use_"); print_cmd_chr(cur_cmd, cur_chr); print_in_mode(mode);
end;
```

**1062.** ⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```
procedure report_illegal_case;
```

```
begin you_cant; help4("Sorry,_but_I'm_not_programmed_to_handle_this_case;")
("I'll_just_pretend_that_you_didn't_ask_for_it.")
("If_you're_in_the_wrong_mode,_you_might_be_able_to")
("return_to_the_right_one_by_typing_I}_or_I$_or_I\par.");
error;
end;
```

**1063.** Some operations are allowed only in privileged modes, i.e., in cases that *mode* > 0. The *privileged* function is used to detect violations of this rule; it issues an error message and returns *false* if the current *mode* is negative.

```

⟨Declare action procedures for use by main_control 1055⟩ +≡
function privileged: boolean;
  begin if mode > 0 then privileged ← true
  else begin report_illegal_case; privileged ← false;
  end;
end;

```

**1064.** Either `\dump` or `\end` will cause *main\_control* to enter the endgame, since both of them have ‘*stop*’ as their command code.

```

⟨Put each of TEX’s primitives into the hash table 232⟩ +≡
  primitive("end", stop, 0);
  primitive("dump", stop, 1);

```

**1065.** ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +≡  
*stop*: **if** *chr\_code* = 1 **then** *print\_esc*("dump") **else** *print\_esc*("end");

**1066.** We don’t want to leave *main\_control* immediately when a *stop* command is sensed, because it may be necessary to invoke an `\output` routine several times before things really grind to a halt. (The output routine might even say ‘`\gdef\end{. . .}`’, to prolong the life of the job.) Therefore *its\_all\_over* is *true* only when the current page and contribution list are empty, and when the last output was not a “dead cycle.”

```

⟨Declare action procedures for use by main_control 1055⟩ +≡
function its_all_over: boolean; { do this when \end or \dump occurs }
  label exit;
  begin if privileged then
    begin if (page_head = page_tail) ∧ (head = tail) ∧ (dead_cycles = 0) then
      begin its_all_over ← true; return;
      end;
      back_input; { we will try to end again after ejecting residual material }
      tail_append(new_null_box); width(tail) ← hsize; tail_append(new_glue(fill_glue));
      tail_append(new_penalty(-’10000000000));
      build_page; { append \hbox to \hsize{} \vfill \penalty-’10000000000 }
      end;
      its_all_over ← false;
    exit: end;

```

**1067. Building boxes and lists.** The most important parts of *main\_control* are concerned with T<sub>E</sub>X's chief mission of box-making. We need to control the activities that put entries on vlists and hlists, as well as the activities that convert those lists into boxes. All of the necessary machinery has already been developed; it remains for us to “push the buttons” at the right times.

**1068.** As an introduction to these routines, let's consider one of the simplest cases: What happens when ‘\hrule’ occurs in vertical mode, or ‘\vrule’ in horizontal mode or math mode? The code in *main\_control* is short, since the *scan\_rule\_spec* routine already does most of what is required; thus, there is no need for a special action procedure.

Note that baselineskip calculations are disabled after a rule in vertical mode, by setting *prev\_depth* ← *ignore\_depth*.

```
⟨ Cases of main_control that build boxes and lists 1068 ⟩ ≡
vmode + hrule, hmode + vrule, mmode + vrule: begin tail_append(scan_rule_spec);
  if abs(mode) = vmode then prev_depth ← ignore_depth
  else if abs(mode) = hmode then space_factor ← 1000;
end;
```

See also sections 1069, 1075, 1079, 1085, 1102, 1104, 1106, 1109, 1114, 1116, 1121, 1124, 1128, 1134, 1138, 1142, 1146, 1149, 1152, 1162, 1166, 1170, 1174, 1176, 1179, 1183, 1187, 1192, 1202, and 1205.

This code is used in section 1057.

**1069.** The processing of things like \hskip and \vskip is slightly more complicated. But the code in *main\_control* is very short, since it simply calls on the action routine *append\_glue*. Similarly, \kern activates *append\_kern*.

```
⟨ Cases of main_control that build boxes and lists 1068 ⟩ +≡
vmode + vskip, hmode + hskip, mmode + hskip, mmode + mskip: append_glue;
any_mode(kern), mmode + mkern: append_kern;
```

**1070.** The *hskip* and *vskip* command codes are used for control sequences like \hss and \vfil as well as for \hskip and \vskip. The difference is in the value of *cur\_chr*.

```
define fil_code = 0 { identifies \hfil and \vfil }
define fill_code = 1 { identifies \hfill and \vfill }
define ss_code = 2 { identifies \hss and \vss }
define fil_neg_code = 3 { identifies \hfilneg and \vfilneg }
define skip_code = 4 { identifies \hskip and \vskip }
define mskip_code = 5 { identifies \mskip }
⟨ Put each of TEX's primitives into the hash table 232 ⟩ +≡
  primitive("hskip", hskip, skip_code);
  primitive("hfil", hskip, fil_code); primitive("hfill", hskip, fill_code);
  primitive("hss", hskip, ss_code); primitive("hfilneg", hskip, fil_neg_code);
  primitive("vskip", vskip, skip_code);
  primitive("vfil", vskip, fil_code); primitive("vfill", vskip, fill_code);
  primitive("vss", vskip, ss_code); primitive("vfilneg", vskip, fil_neg_code);
  primitive("mskip", mskip, mskip_code);
  primitive("kern", kern, explicit); primitive("mkern", mkern, mu_glue);
```

**1071.** ⟨Cases of *print\_cmd\_chr* for symbolic printing of primitives 233⟩ +≡

```

hskip: case chr_code of
  skip_code: print_esc("hskip");
  fil_code: print_esc("hfil");
  fill_code: print_esc("hfill");
  ss_code: print_esc("hss");
  othercases print_esc("hfilneg")
endcases;
vskip: case chr_code of
  skip_code: print_esc("vskip");
  fil_code: print_esc("vfil");
  fill_code: print_esc("vfill");
  ss_code: print_esc("vss");
  othercases print_esc("vfilneg")
endcases;
mskip: print_esc("mskip");
kern: print_esc("kern");
mkern: print_esc("mkern");

```

**1072.** All the work relating to glue creation has been relegated to the following subroutine. It does not call *build\_page*, because it is used in at least one place where that would be a mistake.

⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```

procedure append_glue;
  var s: small_number; { modifier of skip command }
  begin s ← cur_chr;
  case s of

  if s ≥ skip_code then
    begin decr(glue_ref_count(cur_val));
    if s > skip_code then subtype(tail) ← mu_glue;
    end;
  end;

```

**1073.** ⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```

procedure append_kern;
  var s: quarterword; { subtype of the kern node }
  begin s ← cur_chr; scan_dimen(s = mu_glue, false, false); inhibit_glue_flag ← false;
  if ¬is_char_node(tail) ∧ (type(tail) = disp_node) then
    begin prev_append(new_kern(cur_val)); subtype(prev_node) ← s;
    end
  else begin tail_append(new_kern(cur_val)); subtype(tail) ← s;
  end;
end;

```

**1074.** Many of the actions related to box-making are triggered by the appearance of braces in the input. For example, when the user says ‘\hbox to 100pt{\hlist}’ in vertical mode, the information about the box size (100pt, *exactly*) is put onto *save\_stack* with a level boundary word just above it, and *cur\_group* ← *adjusted\_hbox\_group*; T<sub>E</sub>X enters restricted horizontal mode to process the hlist. The right brace eventually causes *save\_stack* to be restored to its former state, at which time the information about the box size (100pt, *exactly*) is available once again; a box is packaged and we leave restricted horizontal mode, appending the new box to the current list of the enclosing mode (in this case to the current list of vertical mode), followed by any vertical adjustments that were removed from the box by *hpack*.

The next few sections of the program are therefore concerned with the treatment of left and right curly braces.

**1075.** If a left brace occurs in the middle of a page or paragraph, it simply introduces a new level of grouping, and the matching right brace will not have such a drastic effect. Such grouping affects neither the mode nor the current list.

```

⟨Cases of main_control that build boxes and lists 1068⟩ +≡
non_math(left_brace): new_save_level(simple_group);
any_mode(begin_group): new_save_level(semi_simple_group);
any_mode(end_group): if cur_group = semi_simple_group then unsave
  else off_save;

```

**1076.** We have to deal with errors in which braces and such things are not properly nested. Sometimes the user makes an error of commission by inserting an extra symbol, but sometimes the user makes an error of omission. T<sub>E</sub>X can't always tell one from the other, so it makes a guess and tries to avoid getting into a loop.

The *off\_save* routine is called when the current group code is wrong. It tries to insert something into the user's input that will help clean off the top level.

```

⟨Declare action procedures for use by main_control 1055⟩ +≡
procedure off_save;
  var p: pointer; {inserted token}
  begin if cur_group = bottom_level then ⟨Drop current token and complain that it was unmatched 1078⟩
  else begin back_input; p ← get_aval; link(temp_head) ← p; print_err("Missing_");
    ⟨Prepare to insert a token that matches cur_group, and print what it is 1077⟩;
    print("_inserted"); ins_list(link(temp_head));
    help5("I´ve inserted something that you may have forgotten.")
    ("(See the <inserted text> above.)")
    ("With luck, this will get me unwedged. But if you")
    ("really didn't forget anything, try typing `2` now; then")
    ("my insertion and my current dilemma will both disappear."); error;
  end;
end;

```

**1077.** At this point,  $link(temp\_head) = p$ , a pointer to an empty one-word node.

```

⟨Prepare to insert a token that matches cur_group, and print what it is 1077⟩ ≡
  case cur_group of
    semi_simple_group: begin info(p) ← cs_token_flag + frozen_end_group; print_esc("endgroup");
                        end;
    math_shift_group:  begin info(p) ← math_shift_token + "$"; print_char("$");
                        end;
    math_left_group:  begin info(p) ← cs_token_flag + frozen_right; link(p) ← get_avail; p ← link(p);
                        info(p) ← other_token + "."; print_esc("right.");
                        end;
  othercases begin info(p) ← right_brace_token + "}"; print_char("}");
  end
endcases

```

```

1078. ⟨Drop current token and complain that it was unmatched 1078⟩ ≡
  begin print_err("Extra_"); print_cmd_chr(cur_cmd, cur_chr);
  help1("Things_are_pretty_mixed_up,_but_I_think_the_worst_is_over.");
  error;
  end

```

This code is used in section 1076.

**1079.** The routine for a *right\_brace* character branches into many subcases, since a variety of things may happen, depending on *cur\_group*. Some types of groups are not supposed to be ended by a right brace; error messages are given in hopes of pinpointing the problem. Most branches of this routine will be filled in later, when we are ready to understand them; meanwhile, we must prepare ourselves to deal with such errors.

```

```

1082. Here is where we clear the parameters that are supposed to revert to their default values after every paragraph and when internal vertical mode is entered.

$\langle$  Declare action procedures for use by *main\_control* 1055  $\rangle +\equiv$

```

procedure normal_paragraph;
  begin if looseness  $\neq$  0 then eq_word_define(int_base + looseness_code, 0);
  if hang_indent  $\neq$  0 then eq_word_define(dimen_base + hang_indent_code, 0);
  if hang_after  $\neq$  1 then eq_word_define(int_base + hang_after_code, 1);
  if par_shape_ptr  $\neq$  null then eq_define(par_shape_loc, shape_ref, null);
end;

```

**1083.** Now let's turn to the question of how `\hbox` is treated. We actually need to consider also a slightly larger context, since constructions like `\setbox3=\hbox...` and `\leaders\hbox...` and `\lower3.8pt\hbox...` are supposed to invoke quite different actions after the box has been packaged. Conversely, constructions like `\setbox3=` can be followed by a variety of different kinds of boxes, and we would like to encode such things in an efficient way.

In other words, there are two problems: to represent the context of a box, and to represent its type.

The first problem is solved by putting a "context code" on the *save\_stack*, just below the two entries that give the dimensions produced by *scan\_spec*. The context code is either a (signed) shift amount, or it is a large integer  $\geq \text{box\_flag}$ , where  $\text{box\_flag} = 2^{30}$ . Codes  $\text{box\_flag}$  through  $\text{box\_flag} + 255$  represent `\setbox0` through `\setbox255`; codes  $\text{box\_flag} + 256$  through  $\text{box\_flag} + 511$  represent `\global\setbox0` through `\global\setbox255`; code  $\text{box\_flag} + 512$  represents `\shipout`; and codes  $\text{box\_flag} + 513$  through  $\text{box\_flag} + 515$  represent `\leaders`, `\cleaders`, and `\xleaders`.

The second problem is solved by giving the command code *make\_box* to all control sequences that produce a box, and by using the following *chr\_code* values to distinguish between them: *box\_code*, *copy\_code*, *last\_box\_code*, *vsplit\_code*, *vtop\_code*, *vtop\_code + vmode*, and *vtop\_code + hmode*, where the latter two are used denote `\vbox` and `\hbox`, respectively.

```

define box_flag  $\equiv$  '1000000000' { context code for '\setbox0' }
define ship_out_flag  $\equiv$  box_flag + 512 { context code for '\shipout' }
define leader_flag  $\equiv$  box_flag + 513 { context code for '\leaders' }
define box_code = 0 { chr_code for '\box' }
define copy_code = 1 { chr_code for '\copy' }
define last_box_code = 2 { chr_code for '\lastbox' }
define vsplit_code = 3 { chr_code for '\vsplit' }
define vtop_code = 4 { chr_code for '\vtop' }

```

(Put each of T<sub>E</sub>X's primitives into the hash table 232)  $\equiv$

```

primitive("moveleft", hmove, 1); primitive("moveright", hmove, 0);
primitive("raise", vmove, 1); primitive("lower", vmove, 0);

primitive("box", make_box, box_code); primitive("copy", make_box, copy_code);
primitive("lastbox", make_box, last_box_code); primitive("vsplit", make_box, vsplit_code);

   $s \leftarrow \text{mem}[p - 1].sc$ ;  $l \leftarrow \text{mem}[p].sc$ ;
  end

```

This code is used in section 1157.

**1162.** Subformulas of math formulas cause a new level of math mode to be entered, on the semantic nest as well as the save stack. These subformulas arise in several ways: (1) A left brace by itself indicates the beginning of a subformula that will be put into a box, thereby freezing its glue and preventing line breaks. (2) A subscript or superscript is treated as a subformula if it is not a single character; the same applies to the nucleus of things like `\underline`. (3) The `\left` primitive initiates a subformula that will be terminated by a matching `\right`. The group codes placed on *save\_stack* in these three cases are *math\_group*, *math\_group*, and *math\_left\_group*, respectively.

Here is the code that handles case (1); the other cases are not quite as trivial, so we shall consider them later.

```

⟨ Cases of main_control that build boxes and lists 1068 ⟩ +≡
 $\text{mmode} + \text{left\_brace}$ : begin  $\text{tail\_append}(\text{new\_noad})$ ;  $\text{back\_input}$ ;  $\text{scan\_math}(\text{nucleus}(\text{tail}), \text{kcode\_noad}(\text{tail}))$ ;
end;

```

**1163.** Recall that the *nucleus*, *subscr*, and *supscr* fields in a noad are broken down into subfields called *math\_type* and either *info* or (*fam*, *character*). The job of *scan\_math* is to figure out what to place in one of these principal fields; it looks at the subformula that comes next in the input, and places an encoding of that subformula into a given word of *mem*.

```

define fam_in_range  $\equiv ((cur\_fam \geq 0) \wedge (cur\_fam < 16))$

  resume_after_display

```

This code is used in section 1206.

**1212.** ⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```

procedure resume_after_display;
  begin if cur_group ≠ math_shift_group then confusion("display");
  unsave; prev_graf ← prev_graf + 3; push_nest; adjust_dir ← abs(direction); mode ← hmode;
  space_factor ← 1000; set_cur_lang; clang ← cur_lang;
  prev_graf ← (norm_min(left_hyphen_min) * '100 + norm_min(right_hyphen_min)) * '200000 + cur_lang;
  ⟨Scan an optional space 454⟩;
  if nest_ptr = 1 then build_page;
  end;

```

**1213.** The user can force the equation number to go on a separate line by causing its width to be zero.  
 ⟨ Squeeze the equation as much as possible; if there is an equation number that should go on a separate line by itself, set  $e \leftarrow 0$  1213 ⟩ ≡

```

begin if (e ≠ 0) ∧ ((w - total_shrink[normal] + q ≤ z) ∨
  (total_shrink[fil] ≠ 0) ∨ (total_shrink[fill] ≠ 0) ∨ (total_shrink[filll] ≠ 0)) then
  begin delete_glue_ref(space_ptr(b)); delete_glue_ref(xspace_ptr(b)); free_node(b, box_node_size);
  b ← hpack(p, z - q, exactly);
  end
else begin e ← 0;
  if w > z then
    begin delete_glue_ref(space_ptr(b)); delete_glue_ref(xspace_ptr(b)); free_node(b, box_node_size);
    b ← hpack(p, z, exactly);
    end;
  end;
  w ← width(b);
end

```

This code is used in section 1211.

**1214.** We try first to center the display without regard to the existence of the equation number. If that would make it too close (where “too close” means that the space between display and equation number is less than the width of the equation number), we either center it in the remaining space or move it as far from the equation number as possible. The latter alternative is taken only if the display begins with glue, since we assume that the user put glue there to control the spacing precisely.

⟨ Determine the displacement,  $d$ , of the left edge of the equation, with respect to the line size  $z$ , assuming that  $l = false$  1214 ⟩ ≡

```

d ← half(z - w);
if (e > 0) ∧ (d < 2 * e) then { too close }
  begin d ← half(z - w - e);
  if p ≠ null then
    if ¬is_char_node(p) then
      if type(p) = glue_node then d ← 0;
    end
  end

```

This code is used in section 1211.

**1215.** If the equation number is set on a line by itself, either before or after the formula, we append an infinite penalty so that no page break will separate the display from its number; and we use the same size and displacement for all three potential lines of the display, even though ‘\parshape’ may specify them differently.

⟨ Append the glue or equation number preceding the display 1215 ⟩ ≡

```

tail_append(new_penalty(pre_display_penalty));
if (d + s ≤ pre_display_size) ∨ l then { not enough clearance }
  begin g1 ← above_display_skip_code; g2 ← below_display_skip_code;
  end
else begin g1 ← above_display_short_skip_code; g2 ← below_display_short_skip_code;
  end;
if l ∧ (e = 0) then { it follows that type(a) = hlist_node }
  begin shift_amount(a) ← s; append_to_vlist(a); tail_append(new_penalty(inf_penalty));
  end
else tail_append(new_param_glue(g1))

```

This code is used in section 1211.

**1216.**  $\langle$  Append the display and perhaps also the equation number 1216  $\rangle \equiv$

```

if  $e \neq 0$  then
  begin  $r \leftarrow new\_kern(z - w - e - d)$ ;
  if  $l$  then
    begin  $link(a) \leftarrow r$ ;  $link(r) \leftarrow b$ ;  $b \leftarrow a$ ;  $d \leftarrow 0$ ;
    end
  else begin  $link(b) \leftarrow r$ ;  $link(r) \leftarrow a$ ;
    end;
   $b \leftarrow hpack(b, natural)$ ;
  end;
   $shift\_amount(b) \leftarrow s + d$ ;  $append\_to\_vlist(b)$ 

```

  end;
   $tail\_append(new\_penalty(post\_display\_penalty))$ ;
  if  $g2 > 0$  then  $tail\_append(new\_param\_glue(g2))$ 

```

This code is used in section 1211.

**1218.** When `\halign` appears in a display, the alignment routines operate essentially as they do in vertical mode. Then the following program is activated, with  $p$  and  $q$  pointing to the beginning and end of the resulting list, and with  $aux\_save$  holding the  $prev\_depth$  value.

$\langle$  Finish an alignment in a display 1218  $\rangle \equiv$

```

begin  $do\_assignments$ ;
if  $cur\_cmd \neq math\_shift$  then  $\langle$  Pontificate about improper alignment in display 1219  $\rangle$ 
else  $\langle$  Check that another $ follows 1209  $\rangle$ ;
   $pop\_nest$ ;  $tail\_append(new\_penalty(pre\_display\_penalty))$ ;
   $tail\_append(new\_param\_glue(above\_display\_skip\_code))$ ;  $link(tail) \leftarrow p$ ;
if  $p \neq null$  then  $tail \leftarrow q$ ;
   $tail\_append(new\_penalty(post\_display\_penalty))$ ;  $tail\_append(new\_param\_glue(below\_display\_skip\_code))$ ;
   $prev\_depth \leftarrow aux\_save.sc$ ;  $resume\_after\_display$ ;
end

```

This code is used in section 823.

**1219.**  $\langle$  Pontificate about improper alignment in display 1219  $\rangle \equiv$

```

begin  $print\_err("Missing\_\$\$\_inserted")$ ;
   $help2("Displays\_can\_use\_special\_alignments\_like\_eqalignno")$ 
   $("only\_if\_nothing\_but\_the\_alignment\_itself\_is\_between\_s.")$ ;  $back\_error$ ;
end

```

This code is used in section 1218.

**1220. Mode-independent processing.** The long *main\_control* procedure has now been fully specified, except for certain activities that are independent of the current mode. These activities do not change the current vlist or hlist or mlist; if they change anything, it is the value of a parameter or the meaning of a control sequence.

Assignments to values in *eqtb* can be global or local. Furthermore, a control sequence can be defined to be ‘\long’ or ‘\outer’, and it might or might not be expanded. The prefixes ‘\global’, ‘\long’, and ‘\outer’ can occur in any order. Therefore we assign binary numeric codes, making it possible to accumulate the union of all specified prefixes by adding the corresponding codes. (Pascal’s *set* operations could also have been used.)

```

⟨Put each of TEX’s primitives into the hash table 232⟩ +≡
  primitive("long", prefix, 1); primitive("outer", prefix, 2); primitive("global", prefix, 4);
  primitive("def", def, 0); primitive("gdef", def, 1); primitive("edef", def, 2); primitive("xdef", def, 3);

```

```

1221. ⟨Cases of print_cmd_chr for symbolic printing of primitives 233⟩ +≡
prefix: if chr_code = 1 then print_esc("long")
      else if chr_code = 2 then print_esc("outer")
      else print_esc("global");
def:   if chr_code = 0 then print_esc("def")
      else if chr_code = 1 then print_esc("gdef")
      else if chr_code = 2 then print_esc("edef")
      else print_esc("xdef");

```

**1222.** Every prefix, and every command code that might or might not be prefixed, calls the action procedure *prefixed\_command*. This routine accumulates a sequence of prefixes until coming to a non-prefix, then it carries out the command.

```

⟨Cases of main_control that don’t depend on mode 1222⟩ ≡

**1223.** If the user says, e.g., ‘\global\global’, the redundancy is silently accepted.

```

⟨Declare action procedures for use by main_control 1055⟩ +≡
⟨Declare subprocedures for prefixed_command 1227⟩
procedure prefixed_command;
  label done, exit;
  var a: small_number; { accumulated prefix codes so far }
      m: integer; { ditto }
      f: internal_font_number; { identifies a font }
      j: halfword; { index into a \parshape specification }
      k: font_index; { index into font_info }
      p, q: pointer; { for temporary short-term use }
      n: integer; { ditto }
      e: boolean; { should a definition be expanded? or was \let not done? }
  begin a ← 0;
  while cur_cmd = prefix do
    begin if ¬odd(a div cur_chr) then a ← a + cur_chr;
    ⟨Get the next non-blank non-relax non-call token 415⟩;
    if cur_cmd ≤ max_non_prefixed_command then ⟨Discard erroneous prefixes and return 1224⟩;
    end;
    ⟨Discard the prefixes \long and \outer if they are irrelevant 1225⟩;
    ⟨Adjust for the setting of \globaldefs 1226⟩;
    case cur_cmd of
      ⟨Assignments 1229⟩
    othercases confusion("prefix")
    endcases;
  done: ⟨Insert a token saved by \afterassignment, if any 1282⟩;
  exit: end;

```

**1224.** ⟨Discard erroneous prefixes and **return** 1224⟩ ≡

```

begin print_err("You can't use a prefix with "); print_cmd_chr(cur_cmd, cur_chr);
print_char(" "); help1("I'll pretend you didn't say \long or \outer or \global.");
back_error; return;
end

```

This code is used in section 1223.

**1225.** ⟨Discard the prefixes \long and \outer if they are irrelevant 1225⟩ ≡

```

if (cur_cmd ≠ def) ∧ (a mod 4 ≠ 0) then
  begin print_err("You can't use "); print_esc("long"); print(" or "); print_esc("outer");
  print(" with "); print_cmd_chr(cur_cmd, cur_chr); print_char(" ");
  help1("I'll pretend you didn't say \long or \outer here."); error;
  end

```

This code is used in section 1223.

**1226.** The previous routine does not have to adjust  $a$  so that  $a \bmod 4 = 0$ , since the following routines test for the `\global` prefix as follows.

```

define global ≡ ( $a \geq 4$ )
define define(#) ≡
    if global then geq_define(#) else eq_define(#)
define word_define(#) ≡
    if global then geq_word_define(#) else eq_word_define(#)

```

⟨ Adjust for the setting of `\globaldefs 1226` ⟩ ≡

```

if global_defs ≠ 0 then
    if global_defs < 0 then
        begin if global then  $a \leftarrow a - 4$ ;
        end
    else begin if  $\neg$ global then  $a \leftarrow a + 4$ ;
    end

```

This code is used in section 1223.

**1227.** When a control sequence is to be defined, by `\def` or `\let` or something similar, the *get\_r\_token* routine will substitute a special control sequence for a token that is not redefinable.

⟨ Declare subprocedures for *prefixed\_command 1227* ⟩ ≡

```

procedure get_r_token;
    label restart;
    begin restart: repeat get_token;
    until cur_tok ≠ space_token;
    if ( $cur\_cs = 0$ ) ∨ ( $cur\_cs > eqtb\_top$ ) ∨ (( $cur\_cs > frozen\_control\_sequence$ ) ∧ ( $cur\_cs \leq eqtb\_size$ )) then
        begin print_err("Missing control sequence inserted");

      end

```

This code is used in section 1306.

**1312. Dumping and undumping the tables.** After INITEX has seen a collection of fonts and macros, it can write all the necessary information on an auxiliary file so that production versions of T<sub>E</sub>X are able to initialize their memory at high speed. The present section of the program takes care of such output and input. We shall consider simultaneously the processes of storing and restoring, so that the inverse relation between them is clear.

The global variable *format\_ident* is a string that is printed right after the *banner* line when T<sub>E</sub>X is ready to start. For INITEX this string says simply '(INITEX)'; for other versions of T<sub>E</sub>X it says, for example, '(preloaded format=plain 1982.11.19)', showing the year, month, and day that the format file was created. We have *format\_ident* = 0 before T<sub>E</sub>X's tables are loaded.

```
<Global variables 13> +≡
format_ident: str_number;
```

```
1313. <Set initial values of key variables 21> +≡
format_ident ← 0;
```

```
1314. <Initialize table entries (done by INITEX only) 170> +≡
if ini_version then format_ident ← "␣(INITEX)";
```

```
1315. <Declare action procedures for use by main_control 1055> +≡
init procedure store_fmt_file;
label found1, found2, done1, done2;
var j, k, l: integer; { all-purpose indices }
    p, q: pointer; { all-purpose pointers }
    x: integer; { something to dump }
    format_engine: ↑text_char;
begin <If dumping is not allowed, abort 1317>;
<Create the format_ident, open the format file, and inform the user that dumping has begun 1341>;
<Dump constants for consistency check 1320>;
<Dump MLTEX-specific data 1414>;
<Dump the string pool 1322>;
<Dump the dynamic memory 1324>;
<Dump the table of equivalents 1326>;
<Dump the font information 1333>;
<Dump the hyphenation tables 1337>;
<Dump a couple more things and the closing check word 1339>;
<Close the format file 1342>;
end;
tini
```

**1316.** Corresponding to the procedure that dumps a format file, we have a function that reads one in. The function returns *false* if the dumped format is incompatible with the present T<sub>E</sub>X table sizes, etc.

```

define bad_fmt = 6666 { go here if the format file is unacceptable }
define too_small(#) ≡
    begin wake_up_terminal; wterm_ln(`---!_Must_increase_the_`, #); goto bad_fmt;
    end
⟨Declare the function called open_fmt_file 535⟩
function load_fmt_file: boolean;
    label bad_fmt, exit;
    var j, k: integer; { all-purpose indices }
        p, q: pointer; { all-purpose pointers }
        x: integer; { something undumped }
        format_engine: ↑text_char; dummy_xord: ASCII_code; dummy_xchr: text_char;
        dummy_xprn: ASCII_code;
    begin ⟨Undump constants for consistency check 1321⟩;
    ⟨Undump MLTEX-specific data 1415⟩;
    ⟨Undump the string pool 1323⟩;
    ⟨Undump the dynamic memory 1325⟩;
    ⟨Undump the table of equivalents 1327⟩;
    ⟨Undump the font information 1334⟩;
    ⟨Undump the hyphenation tables 1338⟩;
    ⟨Undump a couple more things and the closing check word 1340⟩;
    load_fmt_file ← true; return; { it worked! }
bad_fmt: wake_up_terminal; wterm_ln(`Fatal_format_file_error;_I`m_stymied`);
    load_fmt_file ← false;
exit: end;

```

**1317.** The user is not allowed to dump a format file unless *save\_ptr* = 0. This condition implies that *cur\_level* = *level\_one*, hence the *xeq\_level* array is constant and it need not be dumped.

```

⟨If dumping is not allowed, abort 1317⟩ ≡
    if save_ptr ≠ 0 then
        begin print_err("You_can't_dump_inside_a_group"); help1("`{...\\dump}`_is_a_no-no.");
        succumb;
        end

```

This code is used in section 1315.

**1318.** Format files consist of *memory\_word* items, and we use the following macros to dump words of different types:

```

⟨Global variables 13⟩ +≡
fmt_file: word_file; { for input or output of format information }

```

**1319.** The inverse macros are slightly more complicated, since we need to check the range of the values we are reading in. We say ‘*undump(a)(b)(x)*’ to read an integer value  $x$  that is supposed to be in the range  $a \leq x \leq b$ .

```

define undump_end_end(#) ≡ # ← x; end
define undump_end(#) ≡ (x > #) then goto bad_fmt else undump_end_end
define undump(#) ≡
    begin undump_int(x);
    if (x < #) ∨ undump_end
define format_debug_end(#) ≡ write_ln(stderr, ‘_=_’, #);
    end ;
define format_debug(#) ≡
    if debug_format_file then
        begin write(stderr, ‘fmtdebug:’, #); format_debug_end
define undump_size_end_end(#) ≡ too_small(#) else format_debug(#) (x); undump_end_end
define undump_size_end(#) ≡
    if x > # then undump_size_end_end
define undump_size(#) ≡
    begin undump_int(x);
    if x < # then goto bad_fmt;
    undump_size_end

```

**1320.** The next few sections of the program should make it clear how we use the dump/undump macros.

```

⟨Dump constants for consistency check 1320⟩ ≡
    dump_int("57325458); { Web2C TEX's magic constant: "W2TX" }
    { Align engine to 4 bytes with one or more trailing NUL }
    x ← strlen(engine_name); format_engine ← xmalloc_array(text_char, x + 4);
    strcpy(stringcast(format_engine), engine_name);
    for k ← x to x + 3 do format_engine[k] ← 0;
    x ← x + 4 - (x mod 4); dump_int(x); dump_things(format_engine[0], x); libc_free(format_engine);
    dump_int(@$);
    ⟨Dump xord, xchr, and xprn 1400⟩;
    dump_int(max_halfword);
    dump_int(hash_high); dump_int(mem_bot);
    dump_int(mem_top);
    dump_int(egtb_size);
    dump_int(hash_prime);
    dump_int(hyph_prime)

```

This code is used in section 1315.

**1321.** Sections of a WEB program that are “commented out” still contribute strings to the string pool; therefore INITEX and T<sub>E</sub>X will have the same strings. (And it is, of course, a good thing that they do.)

```

**1342.** ⟨Close the format file 1342⟩ ≡  
*w\_close(fmt\_file)*

This code is used in section 1315.

**1343. The main program.** This is it: the part of T<sub>E</sub>X that executes all those procedures we have written.

Well—almost. Let’s leave space for a few more routines that we may have forgotten.

⟨ Last-minute procedures 1346 ⟩

**1344.** We have noted that there are two versions of T<sub>E</sub>X82. One, called `INITEX`, has to be run first; it initializes everything from scratch, without reading a format file, and it has the capability of dumping a format file. The other one is called ‘`VIRTEX`’; it is a “virgin” program that needs to input a format file in order to get started. `VIRTEX` typically has more memory capacity than `INITEX`, because it does not need the space consumed by the auxiliary hyphenation tables and the numerous calls on *primitive*, etc.

The `VIRTEX` program cannot read a format file instantaneously, of course; the best implementations therefore allow for production versions of T<sub>E</sub>X that not only avoid the loading routine for Pascal object code, they also have a format file pre-loaded. This is impossible to do if we stick to standard Pascal; but there is a simple way to fool many systems into avoiding the initialization, as follows: (1) We declare a global integer variable called *ready\_already*. The probability is negligible that this variable holds any particular value like 314159 when `VIRTEX` is first loaded. (2) After we have read in a format file and initialized everything, we set *ready\_already* ← 314159. (3) Soon `VIRTEX` will print ‘\*’, waiting for more input; and at this point we interrupt the program and save its core image in some form that the operating system can reload speedily. (4) When that core image is activated, the program starts again at the beginning; but now *ready\_already* = 314159 and all the other global variables have their initial values too. The former chastity has vanished!

In other words, if we allow ourselves to test the condition *ready\_already* = 314159, before *ready\_already* has been assigned a value, we can avoid the lengthy initialization. Dirty tricks rarely pay off so handsomely.

On systems that allow such preloading, the standard program called `TEX` should be the one that has `plain` format preloaded, since that agrees with *The T<sub>E</sub>Xbook*. Other versions, e.g., `AmSTEX`, should also be provided for commonly used formats.

⟨ Global variables 13 ⟩ +≡

*ready\_already*: integer; { a sacrifice of purity for economy }

**1345.** Now this is really it: T<sub>E</sub>X starts and ends here.

The initial test involving *ready\_already* should be deleted if the Pascal runtime system is smart enough to detect such a “mistake.”

**1346.** Here we do whatever is needed to complete T<sub>E</sub>X's job gracefully on the local operating system. The code here might come into play after a fatal error; it must therefore consist entirely of "safe" operations that cannot produce error messages. For example, it would be a mistake to call *str\_room* or *make\_string* at this time, because a call on *overflow* might lead to an infinite loop.

Actually there's one way to get error messages, via *prepare\_mag*; but that can't cause infinite recursion.

This program doesn't bother to close the input files that may still be open.

⟨Last-minute procedures 1346⟩ ≡

```

procedure close_files_and_terminate;
  var k: integer; { all-purpose index }
  begin ⟨Finish the extensions 1391⟩;
  stat if tracing_stats > 0 then ⟨Output statistics about this job 1347⟩; tats
  wake_up_terminal; ⟨Finish the DVI file 653⟩;
  if log_opened then
    begin wlog_cr; a_close(log_file); selector ← selector - 2;
    if selector = term_only then
      begin print_nl("Transcript_written_on"); print_file_name(0, log_name, 0); print_char(".");
      end;
    end;
  print_ln;
  if (edit_name_start ≠ 0) ∧ (interaction > batch_mode) then
    call_edit(str_pool, edit_name_start, edit_name_length, edit_line);
  end;

```

See also sections 1348, 1349, and 1351.

This code is used in section 1343.

**1347.** The present section goes directly to the log file instead of using *print* commands, because there's no need for these strings to take up *str\_pool* memory when a non-**stat** version of T<sub>E</sub>X is being used.

⟨Output statistics about this job 1347⟩ ≡

```

**1351. Debugging.** Once T<sub>E</sub>X is working, you should be able to diagnose most errors with the `\show` commands and other diagnostic features. But for the initial stages of debugging, and for the revelation of really deep mysteries, you can compile T<sub>E</sub>X with a few more aids, including the Pascal runtime checks and its debugger. An additional routine called *debug\_help* will also come into play when you type ‘D’ after an error message; *debug\_help* also occurs just before a fatal error causes T<sub>E</sub>X to succumb.

The interface to *debug\_help* is primitive, but it is good enough when used with a Pascal debugger that allows you to set breakpoints and to read variables and change their values. After getting the prompt ‘debug #’, you type either a negative number (this exits *debug\_help*), or zero (this goes to a location where you can set a breakpoint, thereby entering into dialog with the Pascal debugger), or a positive number *m* followed by an argument *n*. The meaning of *m* and *n* will be clear from the program below. (If *m* = 13, there is an additional argument, *l*.)

```

define breakpoint = 888 { place where a breakpoint is desirable }
⟨Last-minute procedures 1346⟩ +=
debug procedure debug_help; { routine to display various things }
label breakpoint, exit;
var k, l, m, n: integer;
begin loop
  begin wake_up_terminal; print_nl("debug_#_(-1_to_exit):"); update_terminal; read(term_in, m);
  if m < 0 then return
  else if m = 0 then dump_core { do something to cause a core dump }
    else begin read(term_in, n);
      case m of
        ⟨Numbered cases for debug_help 1352⟩
      othercases print("?")
      endcases;
    end;
  end;
exit: end;
gubed

```

This code is used in section 1351.

**1353. Extensions.** The program above includes a bunch of “hooks” that allow further capabilities to be added without upsetting T<sub>E</sub>X’s basic structure. Most of these hooks are concerned with “whatsit” nodes, which are intended to be used for special purposes; whenever a new extension to T<sub>E</sub>X involves a new kind of whatsit node, a corresponding change needs to be made to the routines below that deal with such nodes, but it will usually be unnecessary to make many changes to the other parts of this program.

In order to demonstrate how extensions can be made, we shall treat ‘\write’, ‘\openout’, ‘\closeout’, ‘\immediate’, ‘\special’, and ‘\setlanguage’ as if they were extensions. These commands are actually primitives of T<sub>E</sub>X, and they should appear in all implementations of the system; but let’s try to imagine that they aren’t. Then the program below illustrates how a person could add them.

Sometimes, of course, an extension will require changes to T<sub>E</sub>X itself; no system of hooks could be complete enough for all conceivable extensions. The features associated with ‘\write’ are almost all confined to the following paragraphs, but there are small parts of the *print.ln* and *print.char* procedures that were introduced specifically to \write characters. Furthermore one of the token lists recognized by the scanner is a *write.text*; and there are a few other miscellaneous places where we have already provided for some aspect of \write. The goal of a T<sub>E</sub>X extender should be to minimize alterations to the standard parts of the program, and to avoid them completely if possible. He or she should also be quite sure that there’s no easy way to accomplish the desired goals with the standard features that T<sub>E</sub>X already has. “Think thrice before extending,” because that may save a lot of work, and it will also keep incompatible extensions of T<sub>E</sub>X from proliferating.

**1354.** First let’s consider the format of whatsit nodes that are used to represent the data associated with \write and its relatives. Recall that a whatsit has *type* = *whatsit.node*, and the *subtype* is supposed to distinguish different kinds of whatsits. Each node occupies two or more words; the exact number is immaterial, as long as it is readily determined from the *subtype* or other data.

We shall introduce five *subtype* values here, corresponding to the control sequences \openout, \write, \closeout, \special, and \setlanguage. The second word of I/O whatsits has a *write.stream* field that identifies the write-stream number (0 to 15, or 16 for out-of-range and positive, or 17 for out-of-range and negative). In the case of \write and \special, there is also a field that points to the reference count of a token list that should be sent. In the case of \openout, we need three words and three auxiliary subfields to hold the string numbers for name, area, and extension.

```

define write_node_size = 2 { number of words in a write/whatsit node }
define open_node_size = 3 { number of words in an open/whatsit node }
define open_node = 0 { subtype in whatsits that represent files to \openout }
define write_node = 1 { subtype in whatsits that represent things to \write }
define close_node = 2 { subtype in whatsits that represent streams to \closeout }
define special_node = 3 { subtype in whatsits that represent \special things }
define language_node = 4 { subtype in whatsits that change the current language }
define what.lang(#) ≡ link(# + 1) { language number, in the range 0 .. 255 }
define what.lhm(#) ≡ type(# + 1) { minimum left fragment, in the range 1 .. 63 }
define what.rhm(#) ≡ subtype(# + 1) { minimum right fragment, in the range 1 .. 63 }
define write_tokens(#) ≡ link(# + 1) { reference count of token list to write }
define write_stream(#) ≡ info(# + 1) { stream number (0 to 17) }
define open_name(#) ≡ link(# + 1) { string number of file name to open }
define open_area(#) ≡ info(# + 2) { string number of file area for open_name }
define open_ext(#) ≡ link(# + 2) { string number of file extension for open_name }

```

**1355.** The sixteen possible `\write` streams are represented by the `write_file` array. The  $j$ th file is open if and only if `write_open[j] = true`. The last two streams are special; `write_open[16]` represents a stream number greater than 15, while `write_open[17]` represents a negative stream number, and both of these variables are always `false`.

```

⟨ Global variables 13 ⟩ +≡
write_file: array [0 .. 15] of alpha_file;
write_open: array [0 .. 17] of boolean;

```

**1356.** ⟨ Set initial values of key variables 21 ⟩ +≡  
**for**  $k \leftarrow 0$  **to** 17 **do** `write_open[k] ← false`;

**1357.** Extensions might introduce new command codes; but it's best to use `extension` with a modifier, whenever possible, so that `main_control` stays the same.

```

define immediate_code = 4 { command modifier for \immediate }
define set_language_code = 5 { command modifier for \setlanguage }
⟨ Put each of TEX's primitives into the hash table 232 ⟩ +≡
primitive("openout", extension, open_node);
primitive("write", extension, write_node); write_loc ← cur_val;
primitive("closeout", extension, close_node);
primitive("special", extension, special_node);
text(frozen_special) ← "special"; eqtb[frozen_special] ← eqtb[cur_val];
primitive("immediate", extension, immediate_code);
primitive("setlanguage", extension, set_language_code);

```

**1358.** The variable `write_loc` just introduced is used to provide an appropriate error message in case of "runaway" write texts.

```

⟨ Global variables 13 ⟩ +≡
write_loc: pointer; { eqtb address of \write }

```

**1359.** ⟨ Cases of `print_cmd_chr` for symbolic printing of primitives 233 ⟩ +≡  
*extension*: **case** *chr\_code* **of**

        if log_opened then
          begin old_setting  $\leftarrow$  selector;
          if (tracing_online  $\leq$  0) then selector  $\leftarrow$  log_only { Show what we're doing in the log file. }
          else selector  $\leftarrow$  term_and_log; { Show what we're doing. }
          print_nl("\openout"); print_int( $j$ ); print("□=□`");
          print_file_name(cur_name, cur_area, cur_ext); print("□."); print_nl(""); print_ln;
          selector  $\leftarrow$  old_setting;
        end;
      end;
    end;
  end;
end

```

This code is used in section 1386.

**1388.** The presence of `\immediate` causes the `do_extension` procedure to descend to one level of recursion. Nothing happens unless `\immediate` is followed by `\openout`, `\write`, or `\closeout`.

```

⟨Implement \immediate 1388⟩ ≡
  begin get_x_token;
  if (cur_cmd = extension)  $\wedge$  (cur_chr  $\leq$  close_node) then
    begin  $p \leftarrow$  tail; do_extension; { append a whatsit node }
    out_what(tail); { do the action immediately }
    flush_node_list(tail); tail  $\leftarrow$   $p$ ; link( $p$ )  $\leftarrow$  null;
    end
  else back_input;
  end

```

This code is used in section 1361.

**1389.** The `\language` extension is somewhat different. We need a subroutine that comes into play when a character of a non-*clang* language is being appended to the current paragraph.

⟨Declare action procedures for use by *main\_control* 1055⟩ +≡

```
procedure fix_language;
  var l: ASCII_code; { the new current language }
  begin if language ≤ 0 then l ← 0
  else if language > 255 then l ← 0
    else l ← language;
  if l ≠ clang then
    begin new_whatst(language_node, small_node_size); what_lang(tail) ← l; clang ← l;
    what_lhm(tail) ← norm_min(left_hyphen_min); what_rhm(tail) ← norm_min(right_hyphen_min);
    end;
  end;
```

**1390.** ⟨Implement `\setlanguage` 1390⟩ ≡

```
if abs(mode) ≠ hmode then report_illegal_case
else begin new_whatst(language_node, small_node_size); scan_int;
  if cur_val ≤ 0 then clang ← 0
  else if cur_val > 255 then clang ← 0
    else clang ← cur_val;
  what_lang(tail) ← clang; what_lhm(tail) ← norm_min(left_hyphen_min);
  what_rhm(tail) ← norm_min(right_hyphen_min);
  end
```

This code is used in section 1361.

**1391.** ⟨Finish the extensions 1391⟩ ≡

```
for k ← 0 to 15 do
  if write_open[k] then a_close(write_file[k])
```

This code is used in section 1346.

**1392. System-dependent changes for Web2c.** Here are extra variables for Web2c. (This numbering of the system-dependent section allows easy integration of Web2c and e-T<sub>E</sub>X, etc.)

```

⟨Global variables 13⟩ +=
edit_name_start: pool_pointer; { where the filename to switch to starts }
edit_name_length, edit_line: integer; { what line to start editing at }
ipc_on: cinttype; { level of IPC action, 0 for none [default] }
stop_at_space: boolean; { whether more_name returns false for space }

```

**1393.** The *edit\_name\_start* will be set to point into *str\_pool* somewhere after its beginning if T<sub>E</sub>X is supposed to switch to an editor on exit.

```

⟨Set initial values of key variables 21⟩ +=
edit_name_start ← 0; stop_at_space ← true;

```

**1394.** These are used when we regenerate the representation of the first 256 strings.

```

⟨Global variables 13⟩ +=
save_str_ptr: str_number;
save_pool_ptr: pool_pointer;
shellenabledp: cinttype;
restrictedshell: cinttype;
output_comment: ↑char;
k, l: 0 .. 255; { used by ‘Make the first 256 strings’, etc. }

```

**1395.** When debugging a macro package, it can be useful to see the exact control sequence names in the format file. For example, if ten new csnames appear, it’s nice to know what they are, to help pinpoint where they came from. (This isn’t a truly “basic” printing procedure, but that’s a convenient module in which to put it.)

```

⟨Basic printing procedures 58⟩ +=
procedure print_csnames(hstart : integer; hfinish : integer);
  var c, h: integer;
  begin write_ln(stderr, ^fmtdebug:csnames_□from□^, hstart, ^□to□^, hfinish, ^: ^);
  for h ← hstart to hfinish do
    begin if text(h) > 0 then
      begin { if have anything at this position }
      for c ← str_start[text(h)] to str_start[text(h) + 1] - 1 do
        begin put_byte(str_pool[c], stderr); { print the characters }
        end;
      write_ln(stderr, ^|^);
      end;
    end;
  end;

```

**1396.** Are we printing extra info as we read the format file?

```

⟨Global variables 13⟩ +=
debug_format_file: boolean;

```

```

1397. ⟨Set initial values of key variables 21⟩ +=
debug debug_format_file ← true; gubed;

```

**1398.** A helper for printing file:line:error style messages. Look for a filename in *full\_source\_filename\_stack*, and if we fail to find one fall back on the non-file:line:error style.

⟨Basic printing procedures 58⟩ +=

```

procedure print_file_line;
  var level: 0 .. max_in_open;
  begin level ← in_open;
  while (level > 0) ∧ (full_source_filename_stack[level] = 0) do decr(level);
  if level = 0 then print_nl("! ")
  else begin print_nl(""); print(full_source_filename_stack[level]); print(":");
    if level = in_open then print_int(line)
    else print_int(line_stack[level + 1]);
    print(": ");
  end;
end;

```

**1399.** To be able to determine whether `\write18` is enabled from within TEX we also implement `\eof18`. We sort of cheat by having an additional route *scan\_four\_bit\_int\_or\_18* which is the same as *scan\_four\_bit\_int* except it also accepts the value 18.

⟨Declare procedures that scan restricted classes of integers 444⟩ +=

```

procedure scan_four_bit_int_or_18;
  begin scan_int;
  if (cur_val < 0) ∨ ((cur_val > 15) ∧ (cur_val ≠ 18)) then
    begin print_err("Bad_number");
    help2("Since I expected to read a number between 0 and 15,")
    ("I changed this one to zero."); int_error(cur_val); cur_val ← 0;
    end;
  end;

```

**1400.** Dumping the *xord*, *xchr*, and *xprn* arrays. We dump these always in the format, so a TCX file loaded during format creation can set a default for users of the format.

⟨Dump *xord*, *xchr*, and *xprn* 1400⟩ ≡

```
dump_things(xord[0], 256); dump_things(xchr[0], 256); dump_things(xprn[0], 256);
```

This code is used in section 1320.

**1401.** Undumping the *xord*, *xchr*, and *xprn* arrays. This code is more complicated, because we want to ensure that a TCX file specified on the command line will override whatever is in the format. Since the tcx file has already been loaded, that implies throwing away the data in the format. Also, if no *translate\_filename* is given, but *eight\_bit\_p* is set we have to make all characters printable.

⟨Undump *xord*, *xchr*, and *xprn* 1401⟩ ≡

```

if translate_filename then
  begin for k ← 0 to 255 do undump_things(dummy_xord, 1);
  for k ← 0 to 255 do undump_things(dummy_xchr, 1);
  for k ← 0 to 255 do undump_things(dummy_xprn, 1);
  end
else begin undump_things(xord[0], 256); undump_things(xchr[0], 256); undump_things(xprn[0], 256);
  if eight_bit_p then
    for k ← 0 to 255 do xprn[k] ← 1;
  end;

```

This code is used in section 1321.

**1402. The string recycling routines.** T<sub>E</sub>X uses 2 upto 4 *new* strings when scanning a filename in an `\input`, `\openin`, or `\openout` operation. These strings are normally lost because the reference to them are not saved after finishing the operation. *search\_string* searches through the string pool for the given string and returns either 0 or the found string number.

```

⟨Declare additional routines for string recycling 1402⟩ ≡
function search_string(search : str_number): str_number;
  label found;
  var result: str_number; s: str_number; {running index}
      len: integer; {length of searched string}
  begin result ← 0; len ← length(search);
  if len = 0 then {trivial case}
    begin result ← ""; goto found;
  end
  else begin s ← search - 1; {start search with newest string below s; search > 1!}
    while s > 255 do {first 256 strings depend on implementation!!}
      begin if length(s) = len then
        if str_eq_str(s, search) then
          begin result ← s; goto found;
        end;
        decr(s);
      end;
    end;
  end;
found: search_string ← result;
end;

```

See also section 1403.

This code is used in section 48.

**1403.** The following routine is a variant of *make\_string*. It searches the whole string pool for a string equal to the string currently built and returns a found string. Otherwise a new string is created and returned. Be cautious, you can not apply *flush\_string* to a replaced string!

```

⟨Declare additional routines for string recycling 1402⟩ +≡
function slow_make_string: str_number;
  label exit;
  var s: str_number; {result of search_string}
      t: str_number; {new string}
  begin t ← make_string; s ← search_string(t);
  if s > 0 then
    begin flush_string; slow_make_string ← s; return;
  end;
  slow_make_string ← t;
exit: end;

```

**1404. System-dependent changes for ML<sub>T</sub>E<sub>X</sub>.**

The boolean variable *mltex\_p* is set by web2c according to the given command line option (or an entry in the configuration file) before any T<sub>E</sub>X function is called.

```
⟨Global variables 13⟩ +≡  
mltex_p: boolean;
```

**1405.** The boolean variable *mltex\_enabled\_p* is used to enable ML<sub>T</sub>E<sub>X</sub>'s character substitution. It is initialised to *false*. When loading a FMT it is set to the value of the boolean *mltex\_p* saved in the FMT file. Additionally it is set to the value of *mltex\_p* in IniT<sub>E</sub>X.

```
⟨Global variables 13⟩ +≡  
mltex_enabled_p: boolean; { enable character substitution }
```

**1406.** ⟨Set initial values of key variables 21⟩ +≡

```
mltex_enabled_p ← false;
```

**1407.** The function *effective\_char* computes the effective character with respect to font information. The effective character is either the base character part of a character substitution definition, if the character does not exist in the font or the character itself.

Inside *effective\_char* we can not use *char\_info* because the macro *char\_info* uses *effective\_char* calling this function a second time with the same arguments.

If neither the character *c* exists in font *f* nor a character substitution for *c* was defined, you can not use the function value as a character offset in *char\_info* because it will access an undefined or invalid *font\_info* entry! Therefore inside *char\_info* and in other places, *effective\_char*'s boolean parameter *err\_p* is set to *true* to issue a warning and return the incorrect replacement, but always existing character *font\_bc[f]*.

⟨Declare additional functions for MLT<sub>E</sub>X 1407⟩ ≡

```

function effective_char(err_p : boolean; f : internal_font_number; c : quarterword): integer;
  label found;
  var base_c : integer; { or eightbits: replacement base character }
      result : integer; { or quarterword }
  begin result ← c; { return c unless it does not exist in the font }
  if ¬mltex_enabled_p then goto found;
  if font_ec[f] ≥ qo(c) then
    if font_bc[f] ≤ qo(c) then
      if char_exists(orig_char_info(f)(c)) then { N.B.: not char_info(f)(c) }
        goto found;
  if qo(c) ≥ char_sub_def_min then
    if qo(c) ≤ char_sub_def_max then
      if char_list_exists(qo(c)) then
        begin base_c ← char_list_char(qo(c)); result ← qi(base_c); { return base_c }
        if ¬err_p then goto found;
        if font_ec[f] ≥ base_c then
          if font_bc[f] ≤ base_c then
            if char_exists(orig_char_info(f)(qi(base_c))) then goto found;
          end;
        if err_p then { print error and return existing character? }
          begin begin_diagnostic; print_nl("Missing_character: There is no ");
            print("substitution for "); print_ASCII(qo(c)); print(" in font "); slow_print(font_name[f]);
            print_char("!"); end_diagnostic(false); result ← qi(font_bc[f]);
            { N.B.: not non-existing character c! }
          end;
        found : effective_char ← result;
      end;

```

See also section 1408.

This code is used in section 571.

**1408.** The function *effective\_char\_info* is equivalent to *char\_info*, except it will return *null\_character* if neither the character *c* exists in font *f* nor is there a substitution definition for *c*. (For these cases *char\_info* using *effective\_char* will access an undefined or invalid *font\_info* entry. See the documentation of *effective\_char* for more information.)

```

⟨Declare additional functions for MLTEX 1407⟩ +=
function effective_char_info(f : internal_font_number; c : quarterword): four_quarters;
  label exit;
  var ci: four_quarters; { character information bytes for c }
    base_c: integer; { or eightbits: replacement base character }
  begin if  $\neg$ mltex_enabled_p then
    begin effective_char_info  $\leftarrow$  orig_char_info(f)(c); return;
    end;
  if font_ec[f]  $\geq$  qo(c) then
    if font_bc[f]  $\leq$  qo(c) then
      begin ci  $\leftarrow$  orig_char_info(f)(c); { N.B.: not char_info(f)(c) }
      if char_exists(ci) then
        begin effective_char_info  $\leftarrow$  ci; return;
        end;
      end;
    if qo(c)  $\geq$  char_sub_def_min then
      if qo(c)  $\leq$  char_sub_def_max then
        if char_list_exists(qo(c)) then
          begin { effective_char_info  $\leftarrow$  char_info(f)(qi(char_list_char(qo(c))));
          base_c  $\leftarrow$  char_list_char(qo(c));
          if font_ec[f]  $\geq$  base_c then
            if font_bc[f]  $\leq$  base_c then
              begin ci  $\leftarrow$  orig_char_info(f)(qi(base_c)); { N.B.: not char_info(f)(c) }
              if char_exists(ci) then
                begin effective_char_info  $\leftarrow$  ci; return;
                end;
              end;
            end;
          end;
        end;
      effective_char_info  $\leftarrow$  null_character;
    exit: end;

```

**1409.** This code is called for a virtual character *c* in *hlist\_out* during *ship\_out*. It tries to build a character substitution construct for *c* generating appropriate DVI code using the character substitution definition for this character. If a valid character substitution exists DVI code is created as if *make\_accent* was used. In all other cases the status of the substitution for this character has been changed between the creation of the character node in the *hlist* and the output of the page—the created DVI code will be correct but the visual result will be undefined.

Former MLT<sub>E</sub>X versions have replaced the character node by a sequence of character, box, and accent kern nodes splicing them into the original horizontal list. This version does not do this to avoid a) a memory overflow at this processing stage, b) additional code to add a pointer to the previous node needed for the replacement, and c) to avoid wrong code resulting in anomalies because of the use within a `\leaders` box.

```

⟨Output a substitution, goto continue if not possible 1409⟩  $\equiv$ 
  begin ⟨Get substitution information, check it, goto found if all is ok, otherwise goto continue 1411⟩;
found: ⟨Print character substitution tracing log 1412⟩;
  ⟨Rebuild character using substitution information 1413⟩;
end

```

This code is used in section 631.

**1410.** The global variables for the code to substitute a virtual character can be declared as local. Nonetheless we declare them as global to avoid stack overflows because *hlist\_out* can be called recursively.

```

⟨Global variables 13⟩ +=
accent_c, base_c, replace_c: integer;
ia_c, ib_c: four_quarters; {accent and base character information}
base_slant, accent_slant: real; {amount of slant}
base_x_height: scaled; {accent is designed for characters of this height}
base_width, base_height: scaled; {height and width for base character}
accent_width, accent_height: scaled; {height and width for accent}
delta: scaled; {amount of right shift}

```

**1411.** Get the character substitution information in *char\_sub\_code* for the character *c*. The current code checks that the substitution exists and is valid and all substitution characters exist in the font, so we can *not* substitute a character used in a substitution. This simplifies the code because we have not to check for cycles in all character substitution definitions.

```

⟨Get substitution information, check it, goto found if all is ok, otherwise goto continue 1411⟩ ≡
  if qo(c) ≥ char_sub_def_min then
    if qo(c) ≤ char_sub_def_max then
      if char_list_exists(qo(c)) then
        begin base_c ← char_list_char(qo(c)); accent_c ← char_list_accent(qo(c));
          if (font_ec[f] ≥ base_c) then
            if (font_bc[f] ≤ base_c) then
              if (font_ec[f] ≥ accent_c) then
                if (font_bc[f] ≤ accent_c) then
                  begin ia_c ← char_info(f)(qi(accent_c)); ib_c ← char_info(f)(qi(base_c));
                    if char_exists(ib_c) then
                      if char_exists(ia_c) then goto found;
                    end;
                  begin_diagnostic; print_nl("Missing_character: Incomplete_substitution");
                  print_ASCII(qo(c)); print("_="); print_ASCII(accent_c); print("_"); print_ASCII(base_c);
                  print("_in_font"); slow_print(font_name[f]); print_char("!"); end_diagnostic(false);
                  goto continue;
                end;
              begin_diagnostic; print_nl("Missing_character: There_is_no"); print("substitution_for");
              print_ASCII(qo(c)); print("_in_font"); slow_print(font_name[f]); print_char("!");
              end_diagnostic(false); goto continue
            end;
          end;
        begin_diagnostic; print_nl("Missing_character: There_is_no"); print("substitution_for");
        print_ASCII(qo(c)); print("_in_font"); slow_print(font_name[f]); print_char("!");
        end_diagnostic(false); goto continue
      end;

```

This code is used in section 1409.

**1412.** For *tracinglostchars* > 99 the substitution is shown in the log file.

```

⟨Print character substitution tracing log 1412⟩ ≡
  if tracing_lost_chars > 99 then
    begin begin_diagnostic; print_nl("Using_character_substitution:"); print_ASCII(qo(c));
      print("_="); print_ASCII(accent_c); print("_"); print_ASCII(base_c); print("_in_font");
      slow_print(font_name[f]); print_char("."); end_diagnostic(false);
    end

```

This code is used in section 1409.

**1413.** This outputs the accent and the base character given in the substitution. It uses code virtually identical to the *make\_accent* procedure, but without the node creation steps.

Additionally if the accent character has to be shifted vertically it does *not* create the same code. The original routine in *make\_accent* and former versions of ML<sub>T</sub>E<sub>X</sub> creates a box node resulting in *push* and *pop* operations, whereas this code simply produces vertical positioning operations. This can influence the pixel rounding algorithm in some DVI drivers—and therefore will probably be changed in one of the next ML<sub>T</sub>E<sub>X</sub> versions.

```

⟨Rebuild character using substitution information 1413⟩ ≡
  base_x_height ← x_height(f); base_slant ← slant(f)/float_constant(65536); accent_slant ← base_slant;
    { slant of accent character font }
  base_width ← char_width(f)(ib_c); base_height ← char_height(f)(height_depth(ib_c));
  accent_width ← char_width(f)(ia_c); accent_height ← char_height(f)(height_depth(ia_c));
    { compute necessary horizontal shift (don't forget slant) }

**1474. System-dependent changes.** This section should be replaced, if necessary, by any special modifications of the program that are necessary to make T<sub>E</sub>X work at a particular installation. It is usually best to design your change file so that all changes to previous sections preserve the section numbering; then everybody's version will be consistent with the published program. More extensive changes, which introduce new sections, can be inserted here; then only the index itself will get a new section number.

**1475.**  $\langle$  Declare action procedures for use by *main\_control* 1055  $\rangle$  +≡

```

**1476.** This function used to be in pdftex, but is useful in tex too.

```

function get_nullstr: str_number;
  begin get_nullstr  $\leftarrow$  "";
  end;

```

**1477. Index.** Here is where you can find all uses of each identifier in the program, with underlined entries pointing to where the identifier was defined. If the identifier is only one letter long, however, you get to see only the underlined entries. *All references are to section numbers instead of page numbers.*

This index also lists error messages and other aspects of the program that you might want to look up some day. For example, the entry for “system dependencies” lists all sections that should receive special attention from people who are installing T<sub>E</sub>X in a new operating environment. A list of various things that can’t happen appears under “this can’t happen”. Approximately 40 sections are listed under “inner loop”; these account for about 60% of T<sub>E</sub>X’s running time, exclusive of input and output.

*z4*: 596.

- ⟨ Accumulate the constant until *cur\_tok* is not a suitable digit 456 ⟩ Used in section 455.
- ⟨ Add the width of node *s* to *act\_width* 882 ⟩ Used in section 880.
- ⟨ Add the width of node *s* to *break\_width* 853 ⟩ Used in section 851.
- ⟨ Add the width of node *s* to *disc\_width* 881 ⟩ Used in section 880.
- ⟨ Adjust for the magnification ratio 468 ⟩ Used in section 464.
- ⟨ Adjust for the setting of `\globaldefs` 1226 ⟩ Used in section 1223.
- ⟨ Adjust *shift\_up* and *shift\_down* for the case of a fraction line 757 ⟩ Used in section 754.
- ⟨ Adjust *shift\_up* and *shift\_down* for the case of no fraction line 756 ⟩ Used in section 754.
- ⟨ Advance *cur\_p* to the node following the present string of characters 878 ⟩ Used in section 877.
- ⟨ Advance past a whatsit node in the *line\_break* loop 1375 ⟩ Used in section 877.
- ⟨ Advance past a whatsit node in the pre-hyphenation loop 1376 ⟩ Used in section 907.
- ⟨ Advance *r*; **goto found** if the parameter delimiter has been fully matched, otherwise **goto continue** 405 ⟩  
Used in section 403.
- ⟨ Allocate entire node *p* and **goto found** 130 ⟩ Used in section 128.
- ⟨ Allocate from the top of node *p* and **goto found** 129 ⟩ Used in section 128.
- ⟨ Apologize for inability to do the operation now, unless `\unskip` follows non-glue 1118 ⟩ Used in section 1117.
- ⟨ Apologize for not loading the font, **goto done** 578 ⟩ Used in section 577.
- ⟨ Append KANJI-KANJI spacing 1462 ⟩ Used in section 1455.
- ⟨ Append KANJI-character *cur\_chr* to the current hlist in the current font; **goto reswitch** when a non-character has been fetched 1469 ⟩  
Used in section 1041.
- ⟨ Append a ligature and/or kern to the translation; **goto continue** if the stack of inserted ligatures is nonempty 921 ⟩ Used in section 917.
- ⟨ Append a new leader node that uses *cur\_box* 1090 ⟩ Used in section 1087.
- ⟨ Append a new letter or a hyphen level 973 ⟩ Used in section 972.
- ⟨ Append a new letter or hyphen 948 ⟩ Used in section 946.
- ⟨ Append a normal inter-word space to the current list, then **goto big\_switch** 1053 ⟩ Used in section 1041.
- ⟨ Append a penalty node, if a nonzero penalty is appropriate 901 ⟩ Used in section 891.
- ⟨ Append an insertion to the current page and **goto contribute** 1019 ⟩ Used in section 1011.
- ⟨ Append any *new\_hlist* entries for *q*, and any appropriate penalties 778 ⟩ Used in section 771.
- ⟨ Append box *cur\_box* to the current list, shifted by *box\_context* 1088 ⟩ Used in section 1087.
- ⟨ Append character *cur\_chr* and the following characters (if any) to the current hlist in the current font; **goto reswitch** when a non-character has been fetched 1045 ⟩ Used in section 1041.
- ⟨ Append characters of *hu[j ..]* to *major\_tail*, advancing *j* 928 ⟩ Used in section 927.
- ⟨ Append inter-element spacing based on *r\_type* and *t* 777 ⟩ Used in section 771.
- ⟨ Append tabskip glue and an empty box to list *u*, and update *s* and *t* as the prototype nodes are passed 820 ⟩  
Used in section 819.
- ⟨ Append the accent with appropriate kerns, then set  $p \leftarrow q$  1137 ⟩ Used in section 1135.
- ⟨ Append the current tabskip glue to the preamble list 789 ⟩ Used in section 788.
- ⟨ Append the display and perhaps also the equation number 1216 ⟩ Used in section 1211.
- ⟨ Append the glue or equation number following the display 1217 ⟩ Used in section 1211.
- ⟨ Append the glue or equation number preceding the display 1215 ⟩ Used in section 1211.
- ⟨ Append the new box to the current vertical list, followed by the list of special nodes taken out of the box by the packager 899 ⟩ Used in section 891.
- ⟨ Append the value *n* to list *p* 949 ⟩ Used in section 948.
- ⟨ Append *disp\_node* at begin of displace area 1470 ⟩ Used in sections 1045, 1136, and 1208.
- ⟨ Append *disp\_node* at end of displace area 1471 ⟩ Used in sections 1047, 1135, 1208, and 1469.
- ⟨ Assign the values  $depth\_threshold \leftarrow show\_box\_depth$  and  $breadth\_max \leftarrow show\_box\_breadth$  242 ⟩  
Used in section 204.
- ⟨ Assignments 1229, 1230, 1233, 1236, 1237, 1238, 1240, 1244, 1247, 1248, 1254, 1255, 1261, 1265, 1266, 1269, 1277, 1423, 1428, 1436, 1441 ⟩ Used in section 1223.
- ⟨ Attach list *p* to the current list, and record its length; then finish up and **return** 1132 ⟩ Used in section 1131.

- ⟨ Attach the limits to  $y$  and adjust  $height(v)$ ,  $depth(v)$  to account for their presence 762 ⟩ Used in section 761.
- ⟨ Back up an outer control sequence so that it can be reread 343 ⟩ Used in section 342.
- ⟨ Basic printing procedures 58, 59, 60, 61, 63, 64, 65, 66, 268, 269, 529, 710, 1368, 1395, 1398, 1467, 1473 ⟩  
Used in section 4.
- ⟨ Break the current page at node  $p$ , put it in box 255, and put the remaining nodes on the contribution list 1028 ⟩ Used in section 1025.
- ⟨ Break the paragraph at the chosen breakpoints, justify the resulting lines to the correct widths, and append them to the current vertical list 887 ⟩ Used in section 826.
- ⟨ Calculate the length,  $l$ , and the shift amount,  $s$ , of the display lines 1161 ⟩ Used in section 1157.
- ⟨ Calculate the natural width,  $w$ , by which the characters of the final line extend to the right of the reference point, plus two ems; or set  $w \leftarrow max\_dimen$  if the non-blank information on that line is affected by stretching or shrinking 1158 ⟩ Used in section 1157.
- ⟨ Call the packaging subroutine, setting  $just\_box$  to the justified box 900 ⟩ Used in section 891.
- ⟨ Call  $try\_break$  if  $cur\_p$  is a legal breakpoint; on the second pass, also try to hyphenate the next word, if  $cur\_p$  is a glue node; then advance  $cur\_p$  to the next node of the paragraph that could possibly be a legal breakpoint 877 ⟩ Used in section 874.
- ⟨ Carry out a ligature replacement, updating the cursor structure and possibly advancing  $j$ ; **goto** *continue* if the cursor doesn't advance, otherwise **goto** *done* 922 ⟩ Used in section 920.
- ⟨ Case statement to copy different types and set  $words$  to the number of initial words not yet copied 212 ⟩  
Used in section 211.
- ⟨ Cases for noads that can follow a  $bin\_noad$  744 ⟩ Used in section 739.
- ⟨ Cases for nodes that can appear in an mlist, after which we **goto** *done\\_with\\_node* 741 ⟩ Used in section 739.
- ⟨ Cases of  $flush\_node\_list$  that arise in mlists only 709 ⟩ Used in section 208.
- ⟨ Cases of  $handle\_right\_brace$  where a  $right\_brace$  triggers a delayed action 1097, 1112, 1130, 1144, 1145, 1180, 1185, 1198 ⟩ Used in section 1080.
- ⟨ Cases of  $main\_control$  that are for extensions to T<sub>E</sub>X 1360 ⟩ Used in section 1057.
- ⟨ Cases of  $main\_control$  that are not part of the inner loop 1057 ⟩ Used in section 1041.
- ⟨ Cases of  $main\_control$  that build boxes and lists 1068, 1069, 1075, 1079, 1085, 1102, 1104, 1106, 1109, 1114, 1116, 1121, 1124, 1128, 1134, 1138, 1142, 1146, 1149, 1152, 1162, 1166, 1170, 1174, 1176, 1179, 1183, 1187, 1192, 1202, 1205 ⟩  
Used in section 1057.
- ⟨ Cases of  $main\_control$  that don't depend on  $mode$  1222, 1281, 1284, 1287, 1289, 1298, 1303, 1432 ⟩  
Used in section 1057.
- ⟨ Cases of  $print\_cmd\_chr$  for symbolic printing of primitives 233, 237, 245, 255, 272, 341, 388, 396, 423, 428, 480, 499, 503, 792, 995, 1065, 1071, 1084, 1101, 1120, 1127, 1155, 1169, 1182, 1191, 1201, 1221, 1232, 1235, 1243, 1264, 1268, 1274, 1276, 1286, 1291, 1300, 1305, 1308, 1359, 1422, 1427, 1434, 1439 ⟩ Used in section 304.
- ⟨ Cases of  $show\_node\_list$  that arise in mlists only 701 ⟩ Used in section 189.
- ⟨ Cases where character is ignored 351 ⟩ Used in section 350.
- ⟨ Change buffered instruction to  $y$  or  $w$  and **goto** *found* 624 ⟩ Used in section 623.
- ⟨ Change buffered instruction to  $z$  or  $x$  and **goto** *found* 625 ⟩ Used in section 623.
- ⟨ Change current mode to  $-vmode$  for  $\backslash halign$ ,  $-hmode$  for  $\backslash valign$  786 ⟩ Used in section 785.
- ⟨ Change discretionary to compulsory and set  $disc\_break \leftarrow true$  893 ⟩ Used in section 892.
- ⟨ Change font  $dvi\_f$  to  $f$  632 ⟩ Used in section 631.
- ⟨ Change state if necessary, and **goto** *switch* if the current character should be ignored, or **goto** *reswitch* if the current character changes to another 350 ⟩ Used in section 349.
- ⟨ Change the case of the token in  $p$ , if a change is appropriate 1302 ⟩ Used in section 1301.
- ⟨ Change the current style and **goto** *delete\\_q* 774 ⟩ Used in section 772.
- ⟨ Change the interaction level and **return** 87 ⟩ Used in section 85.
- ⟨ Change this node to a style node followed by the correct choice, then **goto** *done\\_with\\_node* 742 ⟩  
Used in section 741.
- ⟨ Character  $k$  cannot be printed 50 ⟩ Used in section 49.
- ⟨ Character  $s$  is the current new-line character 250 ⟩ Used in sections 59 and 60.
- ⟨ Check flags of unavailable nodes 176 ⟩ Used in section 173.

- ⟨ Check for charlist cycle 581 ⟩ Used in section 580.
- ⟨ Check for improper alignment in displayed math 787 ⟩ Used in section 785.
- ⟨ Check if node  $p$  is a new champion breakpoint; then **goto** *done* if  $p$  is a forced break or if the page-so-far is already too full 985 ⟩ Used in section 983.
- ⟨ Check if node  $p$  is a new champion breakpoint; then if it is time for a page break, prepare for output, and either fire up the user's output routine and **return** or ship out the page and **goto** *done* 1016 ⟩  
Used in section 1008.
- ⟨ Check single-word *avail* list 174 ⟩ Used in section 173.
- ⟨ Check that another  $\$$  follows 1209 ⟩ Used in sections 1206, 1206, and 1218.
- ⟨ Check that the necessary fonts for math symbols are present; if not, flush the current math lists and set *danger*  $\leftarrow$  *true* 1207 ⟩ Used in sections 1206 and 1206.
- ⟨ Check that the nodes following *hb* permit hyphenation and that at least  $l_{hyf} + r_{hyf}$  letters have been found, otherwise **goto** *done1* 910 ⟩ Used in section 905.
- ⟨ Check the "constant" values for consistency 14, 112, 296, 533, 1262 ⟩ Used in section 1345.
- ⟨ Check the pool check sum 54 ⟩ Used in section 53.
- ⟨ Check variable-size *avail* list 175 ⟩ Used in section 173.
- ⟨ Clean up the memory by removing the break nodes 876 ⟩ Used in sections 826 and 874.
- ⟨ Clear dimensions to zero 661 ⟩ Used in sections 660 and 679.
- ⟨ Clear off top level from *save\_stack* 288 ⟩ Used in section 287.
- ⟨ Close the format file 1342 ⟩ Used in section 1315.
- ⟨ Coerce glue to a dimension 462 ⟩ Used in sections 460 and 466.
- ⟨ Compiler directives 9 ⟩ Used in section 4.
- ⟨ Complain about an undefined family and set *cur\_i* null 734 ⟩ Used in section 733.
- ⟨ Complain about an undefined macro 381 ⟩ Used in section 378.
- ⟨ Complain about missing  $\backslash$ endcsname 384 ⟩ Used in section 383.
- ⟨ Complain about unknown unit and **goto** *done2* 470 ⟩ Used in section 469.
- ⟨ Complain that  $\backslash$ the can't do this; give zero result 439 ⟩ Used in section 424.
- ⟨ Complain that the user should have said  $\backslash$ mathaccent 1178 ⟩ Used in section 1177.
- ⟨ Compleat the incompleat noad 1197 ⟩ Used in section 1196.
- ⟨ Complete a potentially long  $\backslash$ show command 1311 ⟩ Used in section 1306.
- ⟨ Compute result of *multiply* or *divide*, put it in *cur\_val* 1253 ⟩ Used in section 1249.
- ⟨ Compute result of *register* or *advance*, put it in *cur\_val* 1251 ⟩ Used in section 1249.
- ⟨ Compute the amount of skew 752 ⟩ Used in section 749.
- ⟨ Compute the badness,  $b$ , of the current page, using *awful\_bad* if the box is too full 1018 ⟩  
Used in section 1016.
- ⟨ Compute the badness,  $b$ , using *awful\_bad* if the box is too full 986 ⟩ Used in section 985.
- ⟨ Compute the demerits,  $d$ , from  $r$  to *cur\_p* 870 ⟩ Used in section 866.
- ⟨ Compute the discretionary *break\_width* values 851 ⟩ Used in section 848.
- ⟨ Compute the hash code  $h$  267 ⟩ Used in section 265.
- ⟨ Compute the magic offset 776 ⟩ Used in section 1350.
- ⟨ Compute the minimum suitable height,  $w$ , and the corresponding number of extension steps,  $n$ ; also set *width(b)* 725 ⟩ Used in section 724.
- ⟨ Compute the new line width 861 ⟩ Used in section 846.
- ⟨ Compute the register location  $l$  and its type  $p$ ; but **return** if invalid 1250 ⟩ Used in section 1249.
- ⟨ Compute the sum of two glue specs 1252 ⟩ Used in section 1251.
- ⟨ Compute the trie op code,  $v$ , and set  $l \leftarrow 0$  976 ⟩ Used in section 974.
- ⟨ Compute the values of *break\_width* 848 ⟩ Used in section 847.
- ⟨ Consider a node with matching width; **goto** *found* if it's a hit 623 ⟩ Used in section 622.
- ⟨ Consider the demerits for a line from  $r$  to *cur\_p*; deactivate node  $r$  if it should no longer be active; then **goto** *continue* if a line from  $r$  to *cur\_p* is infeasible, otherwise record a new feasible break 862 ⟩  
Used in section 840.
- ⟨ Constants in the outer block 11 ⟩ Used in section 4.

- ⟨ Construct a box with limits above and below it, skewed by *delta* 761 ⟩ Used in section 760.
- ⟨ Construct a sub/superscript combination box *x*, with the superscript offset by *delta* 770 ⟩  
Used in section 767.
- ⟨ Construct a subscript box *x* when there is no superscript 768 ⟩ Used in section 767.
- ⟨ Construct a superscript box *x* 769 ⟩ Used in section 767.
- ⟨ Construct a vlist box for the fraction, according to *shift\_up* and *shift\_down* 758 ⟩ Used in section 754.
- ⟨ Construct an extensible character in a new box *b*, using recipe *rem\_byte(q)* and font *f* 724 ⟩  
Used in section 721.
- ⟨ Contribute an entire group to the current parameter 410 ⟩ Used in section 403.
- ⟨ Contribute the recently matched tokens to the current parameter, and **goto** *continue* if a partial match is still in effect; but abort if *s = null* 408 ⟩ Used in section 403.
- ⟨ Convert a final *bin\_noad* to an *ord\_noad* 740 ⟩ Used in sections 737 and 739.
- ⟨ Convert *cur\_val* to a lower level 440 ⟩ Used in section 424.
- ⟨ Convert math glue to ordinary glue 743 ⟩ Used in section 741.
- ⟨ Convert *nucleus(q)* to an hlist and attach the sub/superscripts 765 ⟩ Used in section 739.
- ⟨ Copy the tabskip glue between columns 806 ⟩ Used in section 802.
- ⟨ Copy the templates from node *cur\_loop* into node *p* 805 ⟩ Used in section 804.
- ⟨ Copy the token list 477 ⟩ Used in section 476.
- ⟨ Create a character node *p* for *nucleus(q)*, possibly followed by a kern node for the italic correction, and set *delta* to the italic correction if a subscript is present 766 ⟩ Used in section 765.
- ⟨ Create a character node *q* for the next character, but set *q* ← *null* if problems arise 1136 ⟩  
Used in section 1135.
- ⟨ Create a new glue specification whose width is *cur\_val*; scan for its stretch and shrink components 473 ⟩  
Used in section 472.
- ⟨ Create a page insertion node with *subtype(r) = qi(n)*, and include the glue correction for box *n* in the current page state 1020 ⟩ Used in section 1019.
- ⟨ Create an active breakpoint representing the beginning of the paragraph 875 ⟩ Used in section 874.
- ⟨ Create and append a discretionary node as an alternative to the unhyphenated word, and continue to develop both branches until they become equivalent 925 ⟩ Used in section 924.
- ⟨ Create equal-width boxes *x* and *z* for the numerator and denominator, and compute the default amounts *shift\_up* and *shift\_down* by which they are displaced from the baseline 755 ⟩ Used in section 754.
- ⟨ Create new active nodes for the best feasible breaks just found 847 ⟩ Used in section 846.
- ⟨ Create the *format\_ident*, open the format file, and inform the user that dumping has begun 1341 ⟩  
Used in section 1315.
- ⟨ Current *mem* equivalent of glue parameter number *n* 230 ⟩ Used in sections 158 and 160.
- ⟨ Deactivate node *r* 871 ⟩ Used in section 862.
- ⟨ Declare action procedures for use by *main\_control* 1055, 1059, 1061, 1062, 1063, 1066, 1072, 1073, 1076, 1081, 1082, 1087, 1091, 1096, 1098, 1103, 1105, 1107, 1108, 1111, 1113, 1115, 1117, 1122, 1125, 1129, 1131, 1135, 1139, 1141, 1143, 1147, 1148, 1150, 1154, 1163, 1167, 1171, 1172, 1175, 1177, 1184, 1186, 1188, 1193, 1203, 1206, 1212, 1223, 1283, 1288, 1292, 1301, 1306, 1315, 1361, 1389, 1468, 1475 ⟩ Used in section 1041.
- ⟨ Declare additional functions for MLT<sub>E</sub>X 1407, 1408 ⟩ Used in section 571.
- ⟨ Declare additional routines for string recycling 1402, 1403 ⟩ Used in section 48.
- ⟨ Declare math construction procedures 745, 746, 747, 748, 749, 754, 760, 763, 767, 773 ⟩ Used in section 737.
- ⟨ Declare procedures for preprocessing hyphenation patterns 955, 959, 960, 964, 968, 970, 971, 977 ⟩  
Used in section 953.
- ⟨ Declare procedures needed for displaying the elements of mlists 702, 703, 705 ⟩ Used in section 185.
- ⟨ Declare procedures needed in *do\_extension* 1362, 1363 ⟩ Used in section 1361.
- ⟨ Declare procedures needed in *hlist\_out*, *vlist\_out* 1381, 1383, 1386, 1448, 1450, 1451, 1465 ⟩ Used in section 630.
- ⟨ Declare procedures needed in *scan\_something\_internal* 1425, 1435, 1440 ⟩ Used in section 424.
- ⟨ Declare procedures that scan font-related stuff 588, 589, 1416 ⟩ Used in section 420.
- ⟨ Declare procedures that scan restricted classes of integers 444, 445, 446, 447, 448, 1399 ⟩ Used in section 420.
- ⟨ Declare subprocedures for *line\_break* 837, 840, 888, 906, 953 ⟩ Used in section 826.

- ⟨ Declare subprocedures for *prefixed\_command* 1227, 1241, 1249, 1256, 1257, 1258, 1259, 1260, 1270, 1278 ⟩  
Used in section 1223.
- ⟨ Declare subprocedures for *var\_delimiter* 720, 722, 723 ⟩ Used in section 717.
- ⟨ Declare the function called *fin\_mlist* 1196 ⟩ Used in section 1186.
- ⟨ Declare the function called *open\_fmt\_file* 535 ⟩ Used in section 1316.
- ⟨ Declare the function called *reconstitute* 917 ⟩ Used in section 906.
- ⟨ Declare the procedure called *align\_peek* 796 ⟩ Used in section 811.
- ⟨ Declare the procedure called *fire\_up* 1023 ⟩ Used in section 1005.
- ⟨ Declare the procedure called *get\_preamble\_token* 793 ⟩ Used in section 785.
- ⟨ Declare the procedure called *handle\_right\_brace* 1080 ⟩ Used in section 1041.
- ⟨ Declare the procedure called *init\_span* 798 ⟩ Used in section 797.
- ⟨ Declare the procedure called *insert\_relax* 390 ⟩ Used in section 377.
- ⟨ Declare the procedure called *macro\_call* 400 ⟩ Used in section 377.
- ⟨ Declare the procedure called *print\_cmd\_chr* 304 ⟩ Used in section 258.
- ⟨ Declare the procedure called *print\_skip\_param* 231 ⟩ Used in section 185.
- ⟨ Declare the procedure called *restore\_trace* 290 ⟩ Used in section 287.
- ⟨ Declare the procedure called *runaway* 312 ⟩ Used in section 120.
- ⟨ Declare the procedure called *show\_token\_list* 298 ⟩ Used in section 120.
- ⟨ Decry the invalid character and **goto** *restart* 352 ⟩ Used in section 350.
- ⟨ Delete *c* – "0" tokens and **goto** *continue* 89 ⟩ Used in section 85.
- ⟨ Delete the page-insertion nodes 1030 ⟩ Used in section 1025.
- ⟨ Destroy the *t* nodes following *q*, and make *r* point to the following node 894 ⟩ Used in section 893.
- ⟨ Determine horizontal glue shrink setting, then **return** or **goto** *common\_ending* 675 ⟩ Used in section 668.
- ⟨ Determine horizontal glue stretch setting, then **return** or **goto** *common\_ending* 669 ⟩ Used in section 668.
- ⟨ Determine the displacement, *d*, of the left edge of the equation, with respect to the line size *z*, assuming that *l* = *false* 1214 ⟩ Used in section 1211.
- ⟨ Determine the shrink order 676 ⟩ Used in sections 675, 687, and 807.
- ⟨ Determine the stretch order 670 ⟩ Used in sections 669, 684, and 807.
- ⟨ Determine the value of *height*(*r*) and the appropriate glue setting; then **return** or **goto** *common\_ending* 683 ⟩ Used in section 679.
- ⟨ Determine the value of *width*(*r*) and the appropriate glue setting; then **return** or **goto** *common\_ending* 668 ⟩  
Used in section 660.
- ⟨ Determine vertical glue shrink setting, then **return** or **goto** *common\_ending* 687 ⟩ Used in section 683.
- ⟨ Determine vertical glue stretch setting, then **return** or **goto** *common\_ending* 684 ⟩ Used in section 683.
- ⟨ Discard erroneous prefixes and **return** 1224 ⟩ Used in section 1223.
- ⟨ Discard the prefixes **\long** and **\outer** if they are irrelevant 1225 ⟩ Used in section 1223.
- ⟨ Dispense with trivial cases of void or bad boxes 989 ⟩ Used in section 988.
- ⟨ Display adjustment *p* 203 ⟩ Used in section 189.
- ⟨ Display box *p* 190 ⟩ Used in section 189.
- ⟨ Display choice node *p* 706 ⟩ Used in section 701.
- ⟨ Display discretionary *p* 201 ⟩ Used in section 189.
- ⟨ Display fraction noad *p* 708 ⟩ Used in section 701.
- ⟨ Display glue *p* 195 ⟩ Used in section 189.
- ⟨ Display insertion *p* 194 ⟩ Used in section 189.
- ⟨ Display kern *p* 197 ⟩ Used in section 189.
- ⟨ Display leaders *p* 196 ⟩ Used in section 195.
- ⟨ Display ligature *p* 199 ⟩ Used in section 189.
- ⟨ Display mark *p* 202 ⟩ Used in section 189.
- ⟨ Display math node *p* 198 ⟩ Used in section 189.
- ⟨ Display node *p* 189 ⟩ Used in section 188.
- ⟨ Display normal noad *p* 707 ⟩ Used in section 701.
- ⟨ Display penalty *p* 200 ⟩ Used in section 189.

- ⟨Display rule  $p$  193⟩ Used in section 189.
- ⟨Display special fields of the unset node  $p$  191⟩ Used in section 190.
- ⟨Display the current context 318⟩ Used in section 317.
- ⟨Display the insertion split cost 1022⟩ Used in section 1021.
- ⟨Display the page break cost 1017⟩ Used in section 1016.
- ⟨Display the token  $(m, c)$  300⟩ Used in section 299.
- ⟨Display the value of  $b$  513⟩ Used in section 509.
- ⟨Display the value of  $glue\_set(p)$  192⟩ Used in section 190.
- ⟨Display the whatsit node  $p$  1369⟩ Used in section 189.
- ⟨Display token  $p$ , and **return** if there are problems 299⟩ Used in section 298.
- ⟨Do first-pass processing based on  $type(q)$ ; **goto** *done\_with\_noad* if a noad has been fully processed, **goto** *check\_dimensions* if it has been translated into *new\_hlist(q)*, or **goto** *done\_with\_node* if a node has been fully processed 739⟩ Used in section 738.
- ⟨Do ligature or kern command, returning to *main\_lig\_loop* or *main\_loop\_wrapup* or *main\_loop\_move* 1052⟩  
Used in section 1051.
- ⟨Do magic computation 326⟩ Used in section 298.
- ⟨Do some work that has been queued up for **\write** 1387⟩ Used in section 1386.
- ⟨Drop current token and complain that it was unmatched 1078⟩ Used in section 1076.
- ⟨D<sub>t</sub>U to other direction 142⟩ Used in section 139.
- ⟨Dump M<sub>L</sub>T<sub>E</sub>X-specific data 1414⟩ Used in section 1315.
- ⟨Dump a couple more things and the closing check word 1339⟩ Used in section 1315.
- ⟨Dump constants for consistency check 1320⟩ Used in section 1315.
- ⟨Dump regions 1 to 4 of *eqtb* 1328⟩ Used in section 1326.
- ⟨Dump regions 5 and 6 of *eqtb* 1329⟩ Used in section 1326.
- ⟨Dump the array info for internal font number  $k$  1335⟩ Used in section 1333.
- ⟨Dump the dynamic memory 1324⟩ Used in section 1315.
- ⟨Dump the font information 1333⟩ Used in section 1315.
- ⟨Dump the hash table 1331⟩ Used in section 1326.
- ⟨Dump the hyphenation tables 1337⟩ Used in section 1315.
- ⟨Dump the string pool 1322⟩ Used in section 1315.
- ⟨Dump the table of equivalentents 1326⟩ Used in section 1315.
- ⟨Dump *xord*, *xchr*, and *xprn* 1400⟩ Used in section 1320.
- ⟨Either append the insertion node  $p$  after node  $q$ , and remove it from the current page, or delete *node(p)* 1033⟩ Used in section 1031.
- ⟨Either insert the material specified by node  $p$  into the appropriate box, or hold it for the next page; also delete node  $p$  from the current page 1031⟩ Used in section 1025.
- ⟨Either process **\ifcase** or set  $b$  to the value of a boolean condition 512⟩ Used in section 509.
- ⟨Empty the last bytes out of *dvi\_buf* 610⟩ Used in section 653.
- ⟨Ensure that box 255 is empty after output 1039⟩ Used in section 1037.
- ⟨Ensure that box 255 is empty before output 1026⟩ Used in section 1025.
- ⟨Ensure that  $trie\_max \geq h + 256$  965⟩ Used in section 964.
- ⟨Enter a hyphenation exception 950⟩ Used in section 946.
- ⟨Enter all of the patterns into a linked trie, until coming to a right brace 972⟩ Used in section 971.
- ⟨Enter as many hyphenation exceptions as are listed, until coming to a right brace; then **return** 946⟩  
Used in section 945.
- ⟨Enter *skip\_blanks* state, emit a space 357⟩ Used in section 353.
- ⟨Error handling procedures 79, 82, 83, 94, 95, 96⟩ Used in section 4.
- ⟨Examine node  $p$  in the hlist, taking account of its effect on the dimensions of the new box, or moving it to the adjustment list; then advance  $p$  to the next node 662⟩ Used in section 660.
- ⟨Examine node  $p$  in the vlist, taking account of its effect on the dimensions of the new box; then advance  $p$  to the next node 680⟩ Used in section 679.
- ⟨Expand a nonmacro 378⟩ Used in section 377.

- ⟨Expand macros in the token list and make *link(def\_ref)* point to the result 1384⟩ Used in section 1383.
- ⟨Expand the next part of the input 489⟩ Used in section 488.
- ⟨Expand the token after the next token 379⟩ Used in section 378.
- ⟨Explain that too many dead cycles have occurred in a row 1035⟩ Used in section 1023.
- ⟨Express astonishment that no number was here 457⟩ Used in section 455.
- ⟨Express consternation over the fact that no alignment is in progress 1140⟩ Used in section 1139.
- ⟨Express shock at the missing left brace; **goto found** 486⟩ Used in section 485.
- ⟨Feed the macro body and its parameters to the scanner 401⟩ Used in section 400.
- ⟨Fetch a box dimension 431⟩ Used in section 424.
- ⟨Fetch a character code from some table 425⟩ Used in section 424.
- ⟨Fetch a font dimension 436⟩ Used in section 424.
- ⟨Fetch a font integer 437⟩ Used in section 424.
- ⟨Fetch a register 438⟩ Used in section 424.
- ⟨Fetch a token list or font identifier, provided that *level = tok\_val* 426⟩ Used in section 424.
- ⟨Fetch an internal dimension and **goto attach\_sign**, or fetch an internal integer 460⟩ Used in section 459.
- ⟨Fetch an item in the current node, if appropriate 435⟩ Used in section 424.
- ⟨Fetch breaking penalty from some table 1442⟩ Used in section 424.
- ⟨Fetch inhibit type from some table 1437⟩ Used in section 424.
- ⟨Fetch something on the *page\_so\_far* 432⟩ Used in section 424.
- ⟨Fetch the *dead\_cycles* or the *insert\_penalties* 430⟩ Used in section 424.
- ⟨Fetch the *par\_shape* size 434⟩ Used in section 424.
- ⟨Fetch the *prev\_graf* 433⟩ Used in section 424.
- ⟨Fetch the *space\_factor* or the *prev\_depth* 429⟩ Used in section 424.
- ⟨Find an active node with fewest demerits 885⟩ Used in section 884.
- ⟨Find hyphen locations for the word in *hc*, or **return** 934⟩ Used in section 906.
- ⟨Find optimal breakpoints 874⟩ Used in section 826.
- ⟨Find the best active node for the desired looseness 886⟩ Used in section 884.
- ⟨Find the best way to split the insertion, and change *type(r)* to *split\_up* 1021⟩ Used in section 1019.
- ⟨Find the glue specification, *main\_p*, for text spaces in the current font 1054⟩ Used in sections 1053 and 1055.
- ⟨Finish an alignment in a display 1218⟩ Used in section 823.
- ⟨Finish displayed math 1211⟩ Used in section 1206.
- ⟨Finish issuing a diagnostic message for an overfull or underfull hbox 674⟩ Used in section 660.
- ⟨Finish issuing a diagnostic message for an overfull or underfull vbox 686⟩ Used in section 679.
- ⟨Finish line, emit a **\par** 359⟩ Used in section 353.
- ⟨Finish line, emit a space 356⟩ Used in sections 353 and 353.
- ⟨Finish line, **goto switch** 358⟩ Used in sections 353 and 353.
- ⟨Finish math in text 1208⟩ Used in section 1206.
- ⟨Finish the DVI file 653⟩ Used in section 1346.
- ⟨Finish the extensions 1391⟩ Used in section 1346.
- ⟨Fire up the user's output routine and **return** 1036⟩ Used in section 1023.
- ⟨Fix the reference count, if any, and negate *cur\_val* if *negative* 441⟩ Used in section 424.
- ⟨Flush the box from memory, showing statistics if requested 650⟩ Used in section 649.
- ⟨Forbidden cases detected in *main\_control* 1060, 1110, 1123, 1156⟩ Used in section 1057.
- ⟨Generate a *down* or *right* command for *w* and **return** 621⟩ Used in section 618.
- ⟨Generate a *y0* or *z0* command in order to reuse a previous appearance of *w* 620⟩ Used in section 618.
- ⟨Get ready to compress the trie 963⟩ Used in section 977.
- ⟨Get ready to start line breaking 827, 838, 845, 859⟩ Used in section 826.
- ⟨Get substitution information, check it, **goto found** if all is ok, otherwise **goto continue** 1411⟩  
Used in section 1409.
- ⟨Get the first line of input and prepare to start 1350⟩ Used in section 1345.
- ⟨Get the next non-blank non-call token 417⟩ Used in sections 416, 452, 466, 514, 537, 588, 796, 802, and 1057.

- ⟨ Get the next non-blank non-relax non-call token 415 ⟩  
Used in sections 414, 1090, 1096, 1163, 1172, 1223, 1238, and 1283.
- ⟨ Get the next non-blank non-sign token; set *negative* appropriately 452 ⟩ Used in sections 451, 459, and 472.
- ⟨ Get the next token, suppressing expansion 366 ⟩ Used in section 365.
- ⟨ Get user's advice and **return** 84 ⟩ Used in section 83.
- ⟨ Give diagnostic information, if requested 1042 ⟩ Used in section 1041.
- ⟨ Give improper `\hyphenation` error 947 ⟩ Used in section 946.
- ⟨ Global variables 13, 20, 26, 31, 33, 40, 51, 55, 74, 77, 80, 97, 105, 116, 117, 118, 119, 125, 171, 179, 187, 219, 252, 259, 262, 277, 292, 303, 307, 310, 311, 314, 315, 316, 339, 354, 369, 375, 393, 398, 399, 421, 449, 458, 491, 500, 504, 523, 524, 531, 538, 543, 550, 560, 561, 566, 603, 606, 616, 627, 657, 658, 672, 695, 730, 735, 775, 781, 825, 832, 834, 836, 839, 844, 850, 858, 883, 903, 911, 916, 918, 932, 937, 954, 958, 961, 982, 991, 993, 1000, 1043, 1086, 1279, 1294, 1312, 1318, 1344, 1355, 1358, 1392, 1394, 1396, 1404, 1405, 1410, 1430, 1446, 1449 ⟩ Used in section 4.
- ⟨ Go into display math mode 1157 ⟩ Used in section 1150.
- ⟨ Go into ordinary math mode 1151 ⟩ Used in sections 1150 and 1154.
- ⟨ Go through the preamble list, determining the column widths and changing the alignrecords to dummy unset boxes 812 ⟩ Used in section 811.
- ⟨ Grow more variable-size memory and **goto restart** 127 ⟩ Used in section 126.
- ⟨ Handle situations involving spaces, braces, changes of state 353 ⟩ Used in section 350.
- ⟨ If a line number class has ended, create new active nodes for the best feasible breaks in that class; then **return** if  $r = last\_active$ , otherwise compute the new *line\_width* 846 ⟩ Used in section 840.
- ⟨ If all characters of the family fit relative to  $h$ , then **goto found**, otherwise **goto not\_found** 966 ⟩  
Used in section 964.
- ⟨ If an alignment entry has just ended, take appropriate action 348 ⟩ Used in section 347.
- ⟨ If an expanded code is present, reduce it and **goto start\_cs** 363 ⟩ Used in section 362.
- ⟨ If dumping is not allowed, abort 1317 ⟩ Used in section 1315.
- ⟨ If instruction  $cur\_i$  is a kern with  $cur\_c$ , attach the kern after  $q$ ; or if it is a ligature with  $cur\_c$ , combine noads  $q$  and  $p$  appropriately; then **return** if the cursor has moved past a noad, or **goto restart** 764 ⟩  
Used in section 763.
- ⟨ If no hyphens were found, **return** 913 ⟩ Used in section 906.
- ⟨ If node  $cur\_p$  is a legal breakpoint, call *try\_break*; then update the active widths by including the glue in *glue\_ptr(cur\_p)* 879 ⟩ Used in section 877.
- ⟨ If node  $p$  is a legal breakpoint, check if this break is the best known, and **goto done** if  $p$  is null or if the page-so-far is already too full to accept more stuff 983 ⟩ Used in section 981.
- ⟨ If node  $q$  is a style node, change the style and **goto delete\_q**; otherwise if it is not a noad, put it into the hlist, advance  $q$ , and **goto done**; otherwise set  $s$  to the size of noad  $q$ , set  $t$  to the associated type (*ord\_noad .. inner\_noad*), and set *pen* to the associated penalty 772 ⟩ Used in section 771.
- ⟨ If node  $r$  is of type *delta\_node*, update *cur\_active\_width*, set *prev\_r* and *prev\_prev\_r*, then **goto continue** 843 ⟩  
Used in section 840.
- ⟨ If the current list ends with a box node, delete it from the list and make *cur\_box* point to it; otherwise set *cur\_box*  $\leftarrow$  *null* 1092 ⟩ Used in section 1091.
- ⟨ If the current page is empty and node  $p$  is to be deleted, **goto done1**; otherwise use node  $p$  to update the state of the current page; if this node is an insertion, **goto contribute**; otherwise if this node is not a legal breakpoint, **goto contribute** or *update\_heights*; otherwise set *pi* to the penalty associated with this breakpoint 1011 ⟩ Used in section 1008.
- ⟨ If the cursor is immediately followed by the right boundary, **goto reswitch**; if it's followed by an invalid character, **goto big\_switch**; otherwise move the cursor one step to the right and **goto main\_lig\_loop** 1047 ⟩  
Used in section 1045.
- ⟨ If the next character is a parameter number, make *cur\_tok* a *match* token; but if it is a left brace, store '*left\_brace, end\_match*', set *hash\_brace*, and **goto done** 487 ⟩ Used in section 485.
- ⟨ If the preamble list has been traversed, check that the row has ended 803 ⟩ Used in section 802.
- ⟨ If the right-hand side is a token parameter or token register, finish the assignment and **goto done** 1239 ⟩  
Used in section 1238.

- ⟨ If the string *hyph\_word*[*h*] is less than *hc*[1 .. *hn*], **goto** *not\_found*; but if the two strings are equal, set *hyf* to the hyphen positions and **goto** *found* 942 ⟩ Used in section 941.
- ⟨ If the string *hyph\_word*[*h*] is less than or equal to *s*, interchange (*hyph\_word*[*h*], *hyph\_list*[*h*]) with (*s*, *p*) 952 ⟩ Used in section 951.
- ⟨ If there's a ligature or kern at the cursor position, update the data structures, possibly advancing *j*; continue until the cursor moves 920 ⟩ Used in section 917.
- ⟨ If there's a ligature/kern command relevant to *cur\_l* and *cur\_r*, adjust the text appropriately; exit to *main\_loop\_wrapup* 1051 ⟩ Used in section 1045.
- ⟨ If this font has already been loaded, set *f* to the internal font number and **goto** *common\_ending* 1273 ⟩ Used in section 1270.
- ⟨ If this *sup\_mark* starts an expanded character like  $\overset{\sim}{A}$  or  $\overset{\sim}{df}$ , then **goto** *reswitch*, otherwise set *state*  $\leftarrow$  *mid\_line* 360 ⟩ Used in section 350.
- ⟨ Ignore the fraction operation and complain about this ambiguous case 1195 ⟩ Used in section 1193.
- ⟨ Implement **\closeout** 1366 ⟩ Used in section 1361.
- ⟨ Implement **\immediate** 1388 ⟩ Used in section 1361.
- ⟨ Implement **\openout** 1364 ⟩ Used in section 1361.
- ⟨ Implement **\setlanguage** 1390 ⟩ Used in section 1361.
- ⟨ Implement **\special** 1367 ⟩ Used in section 1361.
- ⟨ Implement **\write** 1365 ⟩ Used in section 1361.
- ⟨ Incorporate a whatsit node into a vbox 1372 ⟩ Used in section 680.
- ⟨ Incorporate a whatsit node into an hbox 1373 ⟩ Used in section 662.
- ⟨ Incorporate box dimensions into the dimensions of the hbox that will contain it 664 ⟩ Used in section 662.
- ⟨ Incorporate box dimensions into the dimensions of the vbox that will contain it 681 ⟩ Used in section 680.
- ⟨ Incorporate character dimensions into the dimensions of the hbox that will contain it, then move to the next node 665 ⟩ Used in section 662.
- ⟨ Incorporate glue into the horizontal totals 667 ⟩ Used in section 662.
- ⟨ Incorporate glue into the vertical totals 682 ⟩ Used in section 680.
- ⟨ Increase the number of parameters in the last font 591 ⟩ Used in section 589.
- ⟨ Initialize for hyphenating a paragraph 902 ⟩ Used in section 874.
- ⟨ Initialize table entries (done by INITEX only) 170, 228, 234, 238, 246, 256, 264, 563, 957, 962, 1228, 1314, 1382 ⟩ Used in section 8.
- ⟨ Initialize the current page, insert the **\topskip** glue ahead of *p*, and **goto** *continue* 1012 ⟩ Used in section 1011.
- ⟨ Initialize the input routines 337 ⟩ Used in section 1350.
- ⟨ Initialize the output routines 56, 62, 539, 544 ⟩ Used in section 1345.
- ⟨ Initialize the print *selector* based on *interaction* 76 ⟩ Used in sections 1278 and 1350.
- ⟨ Initialize the special list heads and constant nodes 801, 808, 831, 992, 999 ⟩ Used in section 170.
- ⟨ Initialize variables as *ship\_out* begins 628 ⟩ Used in section 651.
- ⟨ Initialize whatever T<sub>E</sub>X might access 8 ⟩ Used in section 4.
- ⟨ Initiate or terminate input from a file 389 ⟩ Used in section 378.
- ⟨ Initiate the construction of an hbox or vbox, then **return** 1095 ⟩ Used in section 1091.
- ⟨ Input and store tokens from the next line of the file 494 ⟩ Used in section 493.
- ⟨ Input for **\read** from the terminal 495 ⟩ Used in section 494.
- ⟨ Input from external file, **goto** *restart* if no input found 349 ⟩ Used in section 347.
- ⟨ Input from token list, **goto** *restart* if end of list or if a parameter needs to be expanded 365 ⟩ Used in section 347.
- ⟨ Input the first line of *read\_file*[*m*] 496 ⟩ Used in section 494.
- ⟨ Input the next line of *read\_file*[*m*] 497 ⟩ Used in section 494.
- ⟨ Insert ASCII-KANJI spacing 1459 ⟩ Used in sections 1452, 1454, and 1458.
- ⟨ Insert KANJI-ASCII spacing 1460 ⟩ Used in sections 1452, 1454, 1454, 1456, 1457, and 1458.
- ⟨ Insert KANJI-KANJI spacing 1461 ⟩ Used in sections 1454 and 1458.
- ⟨ Insert a delta node to prepare for breaks at *cur\_p* 854 ⟩ Used in section 847.

- ⟨Insert a delta node to prepare for the next active node 855⟩ Used in section 847.
- ⟨Insert a dummy node to be sub/superscripted 1189⟩ Used in section 1188.
- ⟨Insert a new active node from *best\_place*[*fit\_class*] to *cur\_p* 856⟩ Used in section 847.
- ⟨Insert a new control sequence after *p*, then make *p* point to it 266⟩ Used in section 265.
- ⟨Insert a new pattern into the linked trie 974⟩ Used in section 972.
- ⟨Insert a new trie node between *q* and *p*, and make *p* point to it 975⟩ Used in section 974.
- ⟨Insert a space after the *last\_char* 1455⟩ Used in section 1453.
- ⟨Insert a space around the character *p* 1452⟩ Used in sections 1451 and 1451.
- ⟨Insert a space before the *first\_char* 1454⟩ Used in section 1453.
- ⟨Insert a token containing *frozen\_endv* 386⟩ Used in section 377.
- ⟨Insert a token saved by `\afterassignment`, if any 1282⟩ Used in section 1223.
- ⟨Insert glue for *split\_top\_skip* and set  $p \leftarrow null$  980⟩ Used in section 979.
- ⟨Insert hbox surround spacing 1453⟩ Used in section 1451.
- ⟨Insert hyphens as specified in *hyph\_list*[*h*] 943⟩ Used in section 942.
- ⟨Insert kinsoku penalty 1443⟩ Used in sections 1050 and 1469.
- ⟨Insert ligature surround spacing 1457⟩ Used in section 1451.
- ⟨Insert macro parameter and **goto restart** 367⟩ Used in section 365.
- ⟨Insert math surround spacing 1456⟩ Used in section 1451.
- ⟨Insert penalty or displace surround spacing 1458⟩ Used in section 1451.
- ⟨Insert the appropriate mark text into the scanner 397⟩ Used in section 378.
- ⟨Insert the current list into its environment 823⟩ Used in section 811.
- ⟨Insert the pair (*s*, *p*) into the exception table 951⟩ Used in section 950.
- ⟨Insert the  $\langle v_j \rangle$  template and **goto restart** 800⟩ Used in section 348.
- ⟨Insert token *p* into T<sub>E</sub>X’s input 332⟩ Used in section 288.
- ⟨Insert *post\_break\_penalty* 1445⟩ Used in sections 1469 and 1469.
- ⟨Insert *pre\_break\_penalty* of *cur\_chr* 1444⟩ Used in section 1469.
- ⟨Interpret code *c* and **return** if done 85⟩ Used in section 84.
- ⟨Introduce new material from the terminal and **return** 88⟩ Used in section 85.
- ⟨Issue an error message if  $cur\_val = fmem\_ptr$  590⟩ Used in section 589.
- ⟨Justify the line ending at breakpoint *cur\_p*, and append it to the current vertical list, together with associated penalties and other insertions 891⟩ Used in section 888.
- ⟨Last-minute procedures 1346, 1348, 1349, 1351⟩ Used in section 1343.
- ⟨Lengthen the preamble periodically 804⟩ Used in section 803.
- ⟨Let *cur\_h* be the position of the first box, and set *leader\_wd* + *lx* to the spacing between corresponding parts of boxes 638⟩ Used in section 637.
- ⟨Let *cur\_v* be the position of the first box, and set *leader\_ht* + *lx* to the spacing between corresponding parts of boxes 647⟩ Used in section 646.
- ⟨Let *d* be the natural width of node *p*; if the node is “visible,” **goto found**; if the node is glue that stretches or shrinks, set  $v \leftarrow max\_dimen$  1159⟩ Used in section 1158.
- ⟨Let *d* be the natural width of this glue; if stretching or shrinking, set  $v \leftarrow max\_dimen$ ; **goto found** in the case of leaders 1160⟩ Used in section 1159.
- ⟨Let *d* be the width of the whatsit *p* 1374⟩ Used in section 1159.
- ⟨Let *m* be the minimal legal code value, based on *cur\_chr* 1245⟩ Used in section 1244.
- ⟨Let *n* be the largest legal code value, based on *cur\_chr* 1246⟩ Used in section 1244.
- ⟨Link node *p* into the current page and **goto done** 1009⟩ Used in section 1008.
- ⟨Local variables for dimension calculations 461, 1417⟩ Used in section 459.
- ⟨Local variables for finishing a displayed formula 1210⟩ Used in section 1206.
- ⟨Local variables for formatting calculations 321⟩ Used in section 317.
- ⟨Local variables for hyphenation 912, 923, 933, 940⟩ Used in section 906.
- ⟨Local variables for initialization 19, 169, 938⟩ Used in section 4.
- ⟨Local variables for line breaking 873, 904⟩ Used in section 826.
- ⟨Look ahead for another character, or leave *lig\_stack* empty if there’s none there 1049⟩ Used in section 1045.

- ⟨Look ahead for glue or kerning 1472⟩ Used in section 1469.
- ⟨Look at all the marks in nodes before the break, and set the final link to *null* at the break 990⟩  
Used in section 988.
- ⟨Look at the list of characters starting with *x* in font *g*; set *f* and *c* whenever a better character is found; **goto found** as soon as a large enough variant is encountered 719⟩ Used in section 718.
- ⟨Look at the other stack entries until deciding what sort of DVI command to generate; **goto found** if node *p* is a “hit” 622⟩ Used in section 618.
- ⟨Look at the variants of  $(z, x)$ ; set *f* and *c* whenever a better character is found; **goto found** as soon as a large enough variant is encountered 718⟩ Used in section 717.
- ⟨Look for parameter number or **##** 490⟩ Used in section 488.
- ⟨Look for the word *hc*[1 .. *hn*] in the exception table, and **goto found** (with *hyf* containing the hyphens) if an entry is found 941⟩ Used in section 934.
- ⟨Look up the characters of list *r* in the hash table, and set *cur\_cs* 385⟩ Used in section 383.
- ⟨Make a copy of node *p* in node *r* 211⟩ Used in section 210.
- ⟨Make a ligature node, if *ligature\_present*; insert a null discretionary, if appropriate 1046⟩  
Used in section 1045.
- ⟨Make a partial copy of the whatsit node *p* and make *r* point to it; set *words* to the number of initial words not yet copied 1370⟩ Used in section 212.
- ⟨Make a second pass over the *m*list, removing all noads and inserting the proper spacing and penalties 771⟩  
Used in section 737.
- ⟨Make final adjustments and **goto done** 587⟩ Used in section 573.
- ⟨Make node *p* look like a *char\_node* and **goto reswitch** 663⟩ Used in sections 633, 662, and 1159.
- ⟨Make sure that *page\_max\_depth* is not exceeded 1014⟩ Used in section 1008.
- ⟨Make sure that *pi* is in the proper range 842⟩ Used in section 840.
- ⟨Make the contribution list empty by setting its tail to *contrib\_head* 1006⟩ Used in section 1005.
- ⟨Make the first 256 strings 49⟩ Used in section 48.
- ⟨Make the height of box *y* equal to *h* 750⟩ Used in section 749.
- ⟨Make the running dimensions in rule *q* extend to the boundaries of the alignment 817⟩ Used in section 816.
- ⟨Make the unset node *r* into a *vlist\_node* of height *w*, setting the glue as if the height were *t* 822⟩  
Used in section 819.
- ⟨Make the unset node *r* into an *hlist\_node* of width *w*, setting the glue as if the width were *t* 821⟩  
Used in section 819.
- ⟨Make variable *b* point to a box for  $(f, c)$  721⟩ Used in section 717.
- ⟨Make *jchr\_widow\_penalty* node 1463⟩ Used in section 1451.
- ⟨Manufacture a control sequence name 383⟩ Used in section 378.
- ⟨Math-only cases in non-math modes, or vice versa 1058⟩ Used in section 1057.
- ⟨Merge the widths in the span nodes of *q* with those of *p*, destroying the span nodes of *q* 814⟩  
Used in section 812.
- ⟨Modify the end of the line to reflect the nature of the break and to include **\rightskip**; also set the proper value of *disc\_break* 892⟩ Used in section 891.
- ⟨Modify the glue specification in *main\_p* according to the space factor 1056⟩ Used in section 1055.
- ⟨Move down or output leaders 645⟩ Used in section 642.
- ⟨Move node *p* to the current page; if it is time for a page break, put the nodes following the break back onto the contribution list, and **return** to the user’s output routine if there is one 1008⟩ Used in section 1005.
- ⟨Move pointer *s* to the end of the current list, and set *replace\_count(r)* appropriately 929⟩  
Used in section 925.
- ⟨Move right or output leaders 636⟩ Used in section 633.
- ⟨Move the characters of a ligature node to *hu* and *hc*; but **goto done3** if they are not all letters 909⟩  
Used in section 908.
- ⟨Move the cursor past a pseudo-ligature, then **goto main\_loop\_lookahead** or *main\_lig\_loop* 1048⟩  
Used in section 1045.
- ⟨Move the data into *trie* 969⟩ Used in section 977.

- ⟨ Move to next line of file, or **goto** *restart* if there is no next line, or **return** if a `\read` line has finished 368 ⟩  
Used in section 349.
- ⟨ Negate all three glue components of *cur\_val* 442 ⟩ Used in section 441.
- ⟨ Nullify *width(q)* and the tabskip glue following this column 813 ⟩ Used in section 812.
- ⟨ Numbered cases for *debug\_help* 1352 ⟩ Used in section 1351.
- ⟨ Open *tfm\_file* for input 574 ⟩ Used in section 573.
- ⟨ Other local variables for *try\_break* 841 ⟩ Used in section 840.
- ⟨ Output a box in a vlist 643 ⟩ Used in section 642.
- ⟨ Output a box in an hlist 634 ⟩ Used in section 633.
- ⟨ Output a leader box at *cur\_h*, then advance *cur\_h* by *leader\_wd + lx* 639 ⟩ Used in section 637.
- ⟨ Output a leader box at *cur\_v*, then advance *cur\_v* by *leader\_ht + lx* 648 ⟩ Used in section 646.
- ⟨ Output a rule in a vlist, **goto** *next\_p* 644 ⟩ Used in section 642.
- ⟨ Output a rule in an hlist 635 ⟩ Used in section 633.
- ⟨ Output a substitution, **goto** *continue* if not possible 1409 ⟩ Used in section 631.
- ⟨ Output leaders in a vlist, **goto** *fin\_rule* if a rule or to *next\_p* if done 646 ⟩ Used in section 645.
- ⟨ Output leaders in an hlist, **goto** *fin\_rule* if a rule or to *next\_p* if done 637 ⟩ Used in section 636.
- ⟨ Output node *p* for *hlist\_out* and move to the next node, maintaining the condition *cur\_v = base\_line* 631 ⟩  
Used in section 630.
- ⟨ Output node *p* for *vlist\_out* and move to the next node, maintaining the condition *cur\_h = left\_edge* 641 ⟩  
Used in section 640.
- ⟨ Output statistics about this job 1347 ⟩ Used in section 1346.
- ⟨ Output the font definitions for all fonts that were used 654 ⟩ Used in section 653.
- ⟨ Output the font name whose internal number is *f* 614 ⟩ Used in section 613.
- ⟨ Output the non-*char\_node* *p* for *hlist\_out* and move to the next node 633 ⟩ Used in section 631.
- ⟨ Output the non-*char\_node* *p* for *vlist\_out* 642 ⟩ Used in section 641.
- ⟨ Output the whatsit node *p* in a vlist 1379 ⟩ Used in section 642.
- ⟨ Output the whatsit node *p* in an hlist 1380 ⟩ Used in section 633.
- ⟨ Pack the family into *trie* relative to *h* 967 ⟩ Used in section 964.
- ⟨ Package an unset box for the current column and record its width 807 ⟩ Used in section 802.
- ⟨ Package the preamble list, to determine the actual tabskip glue amounts, and let *p* point to this prototype box 815 ⟩ Used in section 811.
- ⟨ Perform the default output routine 1034 ⟩ Used in section 1023.
- ⟨ Pontificate about improper alignment in display 1219 ⟩ Used in section 1218.
- ⟨ Pop the condition stack 507 ⟩ Used in sections 509, 511, 520, and 521.
- ⟨ Prepare all the boxes involved in insertions to act as queues 1029 ⟩ Used in section 1025.
- ⟨ Prepare to deactivate node *r*, and **goto** *deactivate* unless there is a reason to consider lines of text from *r* to *cur\_p* 865 ⟩ Used in section 862.
- ⟨ Prepare to insert a token that matches *cur\_group*, and print what it is 1077 ⟩ Used in section 1076.
- ⟨ Prepare to move a box or rule node to the current page, then **goto** *contribute* 1013 ⟩ Used in section 1011.
- ⟨ Prepare to move whatsit *p* to the current page, then **goto** *contribute* 1377 ⟩ Used in section 1011.
- ⟨ Print a short indication of the contents of node *p* 181 ⟩ Used in section 180.
- ⟨ Print a symbolic description of the new break node 857 ⟩ Used in section 856.
- ⟨ Print a symbolic description of this feasible break 867 ⟩ Used in section 866.
- ⟨ Print character substitution tracing log 1412 ⟩ Used in section 1409.
- ⟨ Print either ‘**definition**’ or ‘**use**’ or ‘**preamble**’ or ‘**text**’, and insert tokens that should lead to recovery 345 ⟩ Used in section 344.
- ⟨ Print location of current line 319 ⟩ Used in section 318.
- ⟨ Print newly busy locations 177 ⟩ Used in section 173.
- ⟨ Print string *s* as an error message 1296 ⟩ Used in section 1292.
- ⟨ Print string *s* on the terminal 1293 ⟩ Used in section 1292.
- ⟨ Print the banner line, including the date and time 547 ⟩ Used in section 545.
- ⟨ Print the font identifier for *font(p)* 273 ⟩ Used in sections 180 and 182.

- ⟨Print the help information and **goto** *continue* 90⟩ Used in section 85.
- ⟨Print the list between *printed\_node* and *cur\_p*, then set *printed\_node* ← *cur\_p* 868⟩ Used in section 867.
- ⟨Print the menu of available options 86⟩ Used in section 85.
- ⟨Print the result of command *c* 483⟩ Used in section 481.
- ⟨Print two lines using the tricky pseudoprinted information 323⟩ Used in section 318.
- ⟨Print type of token list 320⟩ Used in section 318.
- ⟨Process an active-character control sequence and set *state* ← *mid\_line* 361⟩ Used in section 350.
- ⟨Process node-or-noad *q* as much as possible in preparation for the second pass of *mlist\_to\_hlist*, then move to the next item in the *mlist* 738⟩ Used in section 737.
- ⟨Process whatsit *p* in *vert\_break* loop, **goto** *not\_found* 1378⟩ Used in section 984.
- ⟨Prune the current list, if necessary, until it contains only *char\_node*, *kern\_node*, *hlist\_node*, *vlist\_node*, *rule\_node*, and *ligature\_node* items; set *n* to the length of the list, and set *q* to the list's tail 1133⟩  
Used in section 1131.
- ⟨Prune unwanted nodes at the beginning of the next line 890⟩ Used in section 888.
- ⟨Pseudoprint the line 324⟩ Used in section 318.
- ⟨Pseudoprint the token list 325⟩ Used in section 318.
- ⟨Push the condition stack 506⟩ Used in section 509.
- ⟨Put each of TeX's primitives into the hash table 232, 236, 244, 254, 271, 340, 387, 395, 422, 427, 479, 498, 502, 564, 791, 994, 1064, 1070, 1083, 1100, 1119, 1126, 1153, 1168, 1181, 1190, 1200, 1220, 1231, 1234, 1242, 1263, 1267, 1275, 1285, 1290, 1299, 1304, 1357, 1421, 1426, 1433, 1438⟩ Used in section 1349.
- ⟨Put help message on the transcript file 91⟩ Used in section 83.
- ⟨Put the characters *hu*[*i* + 1 ..] into *post\_break*(*r*), appending to this list and to *major\_tail* until synchronization has been achieved 927⟩ Used in section 925.
- ⟨Put the characters *hu*[*l* .. *i*] and a hyphen into *pre\_break*(*r*) 926⟩ Used in section 925.
- ⟨Put the fraction into a box with its delimiters, and make *new\_hlist*(*q*) point to it 759⟩ Used in section 754.
- ⟨Put the `\leftskip` glue at the left and detach this line 898⟩ Used in section 891.
- ⟨Put the optimal current page into box 255, update *first\_mark* and *bot\_mark*, append insertions to their boxes, and put the remaining nodes back on the contribution list 1025⟩ Used in section 1023.
- ⟨Put the (positive) 'at' size into *s* 1272⟩ Used in section 1271.
- ⟨Put the `\rightskip` glue after node *q* 897⟩ Used in section 892.
- ⟨Read and check the font data; *abort* if the TFM file is malformed; if there's no room for this font, say so and **goto** *done*; otherwise *incr*(*font\_ptr*) and **goto** *done* 573⟩ Used in section 571.
- ⟨Read box dimensions 582⟩ Used in section 573.
- ⟨Read character data 580⟩ Used in section 573.
- ⟨Read extensible character recipes 585⟩ Used in section 573.
- ⟨Read font parameters 586⟩ Used in section 573.
- ⟨Read ligature/kern program 584⟩ Used in section 573.
- ⟨Read next line of file into *buffer*, or **goto** *restart* if the file has ended 370⟩ Used in section 368.
- ⟨Read one string, but return *false* if the string memory space is getting too tight for comfort 53⟩  
Used in section 52.
- ⟨Read the first line of the new file 549⟩ Used in section 548.
- ⟨Read the other strings from the `TEX.POOL` file and return *true*, or give an error message and return *false* 52⟩ Used in section 48.
- ⟨Read the TFM header 579⟩ Used in section 573.
- ⟨Read the TFM size fields 576⟩ Used in section 573.
- ⟨Readjust the height and depth of *cur\_box*, for `\vtop` 1099⟩ Used in section 1098.
- ⟨Rebuild character using substitution information 1413⟩ Used in section 1409.
- ⟨Reconstitute nodes for the hyphenated word, inserting discretionary hyphens 924⟩ Used in section 914.
- ⟨Record a new feasible break 866⟩ Used in section 862.
- ⟨Recover from an unbalanced output routine 1038⟩ Used in section 1037.
- ⟨Recover from an unbalanced write command 1385⟩ Used in section 1384.
- ⟨Recycle node *p* 1010⟩ Used in section 1008.

- ⟨ Remove the last box, unless it's part of a discretionary 1093 ⟩ Used in section 1092.
- ⟨ Replace nodes *ha* .. *hb* by a sequence of nodes that includes the discretionary hyphens 914 ⟩  
Used in section 906.
- ⟨ Replace the tail of the list by *p* 1199 ⟩ Used in section 1198.
- ⟨ Replace *z* by *z'* and compute  $\alpha, \beta$  583 ⟩ Used in section 582.
- ⟨ Report a runaway argument and abort 407 ⟩ Used in sections 403 and 410.
- ⟨ Report a tight hbox and **goto** *common\_ending*, if this box is sufficiently bad 678 ⟩ Used in section 675.
- ⟨ Report a tight vbox and **goto** *common\_ending*, if this box is sufficiently bad 689 ⟩ Used in section 687.
- ⟨ Report an extra right brace and **goto** *continue* 406 ⟩ Used in section 403.
- ⟨ Report an improper use of the macro and abort 409 ⟩ Used in section 408.
- ⟨ Report an overfull hbox and **goto** *common\_ending*, if this box is sufficiently bad 677 ⟩ Used in section 675.
- ⟨ Report an overfull vbox and **goto** *common\_ending*, if this box is sufficiently bad 688 ⟩ Used in section 687.
- ⟨ Report an underfull hbox and **goto** *common\_ending*, if this box is sufficiently bad 671 ⟩ Used in section 669.
- ⟨ Report an underfull vbox and **goto** *common\_ending*, if this box is sufficiently bad 685 ⟩ Used in section 684.
- ⟨ Report overflow of the input buffer, and abort 36 ⟩ Used in section 32.
- ⟨ Report that an invalid delimiter code is being changed to null; set *cur\_val*  $\leftarrow 0$  1173 ⟩ Used in section 1172.
- ⟨ Report that the font won't be loaded 572 ⟩ Used in section 571.
- ⟨ Report that this dimension is out of range 471 ⟩ Used in section 459.
- ⟨ Resume the page builder after an output routine has come to an end 1037 ⟩ Used in section 1112.
- ⟨ Reverse the links of the relevant passive nodes, setting *cur\_p* to the first breakpoint 889 ⟩  
Used in section 888.
- ⟨ Scan a control sequence and set *state*  $\leftarrow$  *skip\_blanks* or *mid\_line* 362 ⟩ Used in section 350.
- ⟨ Scan a numeric constant 455 ⟩ Used in section 451.
- ⟨ Scan a parameter until its delimiter string has been found; or, if *s* = *null*, simply scan the delimiter string 403 ⟩ Used in section 402.
- ⟨ Scan a subformula enclosed in braces and **return** 1165 ⟩ Used in section 1163.
- ⟨ Scan ahead in the buffer until finding a nonletter; if an expanded code is encountered, reduce it and **goto** *start\_cs*; otherwise if a multiletter control sequence is found, adjust *cur\_cs* and *loc*, and **goto** *found* 364 ⟩ Used in section 362.
- ⟨ Scan an alphabetic character code into *cur\_val* 453 ⟩ Used in section 451.
- ⟨ Scan an optional space 454 ⟩ Used in sections 453, 459, 466, and 1212.
- ⟨ Scan and build the body of the token list; **goto** *found* when finished 488 ⟩ Used in section 484.
- ⟨ Scan and build the parameter part of the macro definition 485 ⟩ Used in section 484.
- ⟨ Scan decimal fraction 463 ⟩ Used in section 459.
- ⟨ Scan file name in the buffer 542 ⟩ Used in section 541.
- ⟨ Scan for all other units and adjust *cur\_val* and *f* accordingly; **goto** *done* in the case of scaled points 469 ⟩  
Used in section 464.
- ⟨ Scan for **fil** units; **goto** *attach\_fraction* if found 465 ⟩ Used in section 464.
- ⟨ Scan for **mu** units and **goto** *attach\_fraction* 467 ⟩ Used in section 464.
- ⟨ Scan for units that are internal dimensions; **goto** *attach\_sign* with *cur\_val* set if found 466 ⟩  
Used in section 464.
- ⟨ Scan preamble text until *cur\_cmd* is *tab\_mark* or *car\_ret*, looking for changes in the tabskip glue; append an alignrecord to the preamble list 790 ⟩ Used in section 788.
- ⟨ Scan the argument for command *c* 482 ⟩ Used in section 481.
- ⟨ Scan the font size specification 1271 ⟩ Used in section 1270.
- ⟨ Scan the parameters and make *link(r)* point to the macro body; but **return** if an illegal **\par** is detected 402 ⟩ Used in section 400.
- ⟨ Scan the preamble and record it in the *preamble* list 788 ⟩ Used in section 785.
- ⟨ Scan the template  $\langle u_j \rangle$ , putting the resulting token list in *hold\_head* 794 ⟩ Used in section 790.
- ⟨ Scan the template  $\langle v_j \rangle$ , putting the resulting token list in *hold\_head* 795 ⟩ Used in section 790.
- ⟨ Scan units and set *cur\_val* to  $x \cdot (cur\_val + f/2^{16})$ , where there are *x* sp per unit; **goto** *attach\_sign* if the units are internal 464 ⟩ Used in section 459.

- ⟨ Search *eqtb* for equivalents equal to *p* 261 ⟩ Used in section 178.
- ⟨ Search *hyph.list* for pointers to *p* 944 ⟩ Used in section 178.
- ⟨ Search *save\_stack* for equivalents that point to *p* 291 ⟩ Used in section 178.
- ⟨ Seek list and make *t* pointing widow penalty position 1464 ⟩ Used in section 1463.
- ⟨ Select the appropriate case and **return** or **goto** *common\_ending* 520 ⟩ Used in section 512.
- ⟨ Set initial values of key variables 21, 23, 24, 75, 78, 81, 98, 172, 221, 260, 263, 278, 293, 355, 376, 394, 450, 492, 501, 562, 567, 604, 607, 617, 659, 673, 696, 782, 939, 1001, 1044, 1280, 1295, 1313, 1356, 1393, 1397, 1406, 1431, 1447 ⟩  
Used in section 8.
- ⟨ Set line length parameters in preparation for hanging indentation 860 ⟩ Used in section 859.
- ⟨ Set the glue in all the unset boxes of the current list 816 ⟩ Used in section 811.
- ⟨ Set the glue in node *r* and change it from an unset node 819 ⟩ Used in section 818.
- ⟨ Set the unset box *q* and the unset boxes in it 818 ⟩ Used in section 816.
- ⟨ Set the value of *b* to the badness for shrinking the line, and compute the corresponding *fit\_class* 864 ⟩  
Used in section 862.
- ⟨ Set the value of *b* to the badness for stretching the line, and compute the corresponding *fit\_class* 863 ⟩  
Used in section 862.
- ⟨ Set the value of *output\_penalty* 1024 ⟩ Used in section 1023.
- ⟨ Set up data structures with the cursor following position *j* 919 ⟩ Used in section 917.
- ⟨ Set up the values of *cur\_size* and *cur\_mu*, based on *cur\_style* 714 ⟩  
Used in sections 731, 737, 741, 765, 771, and 774.
- ⟨ Set variable *c* to the current escape character 249 ⟩ Used in section 64.
- ⟨ Ship box *p* out 651 ⟩ Used in section 649.
- ⟨ Show equivalent *n*, in region 1 or 2 229 ⟩ Used in section 258.
- ⟨ Show equivalent *n*, in region 3 235 ⟩ Used in section 258.
- ⟨ Show equivalent *n*, in region 4 239 ⟩ Used in section 258.
- ⟨ Show equivalent *n*, in region 5 248 ⟩ Used in section 258.
- ⟨ Show equivalent *n*, in region 6 257 ⟩ Used in section 258.
- ⟨ Show the auxiliary field, *a* 225 ⟩ Used in section 224.
- ⟨ Show the current contents of a box 1309 ⟩ Used in section 1306.
- ⟨ Show the current japanese processing mode 1429 ⟩ Used in section 1306.
- ⟨ Show the current meaning of a token, then **goto** *common\_ending* 1307 ⟩ Used in section 1306.
- ⟨ Show the current value of some parameter or register, then **goto** *common\_ending* 1310 ⟩  
Used in section 1306.
- ⟨ Show the font identifier in *eqtb[n]* 240 ⟩ Used in section 239.
- ⟨ Show the halfword code in *eqtb[n]* 241 ⟩ Used in section 239.
- ⟨ Show the status of the current page 997 ⟩ Used in section 224.
- ⟨ Show the text of the macro being expanded 412 ⟩ Used in section 400.
- ⟨ Simplify a trivial box 732 ⟩ Used in section 731.
- ⟨ Skip to **\else** or **\fi**, then **goto** *common\_ending* 511 ⟩ Used in section 509.
- ⟨ Skip to node *ha*, or **goto** *done1* if no hyphenation should be attempted 907 ⟩ Used in section 905.
- ⟨ Skip to node *hb*, putting letters into *hu* and *hc* 908 ⟩ Used in section 905.
- ⟨ Sort *p* into the list starting at *rover* and advance *p* to *rlink(p)* 133 ⟩ Used in section 132.
- ⟨ Sort the hyphenation op tables into proper order 956 ⟩ Used in section 963.
- ⟨ Split off part of a vertical box, make *cur\_box* point to it 1094 ⟩ Used in section 1091.
- ⟨ Squeeze the equation as much as possible; if there is an equation number that should go on a separate line by itself, set  $e \leftarrow 0$  1213 ⟩ Used in section 1211.
- ⟨ Start a new current page 1002 ⟩ Used in section 1028.
- ⟨ Store *cur\_box* in a box register 1089 ⟩ Used in section 1087.
- ⟨ Store maximum values in the *hyf* table 935 ⟩ Used in section 934.
- ⟨ Store *save\_stack[save\_ptr]* in *eqtb[p]*, unless *eqtb[p]* holds a global value 289 ⟩ Used in section 288.
- ⟨ Store the current token, but **goto** *continue* if it is a blank space that would become an undelimited parameter 404 ⟩ Used in section 403.

- ⟨ Subtract glue from *break\_width* 849 ⟩ Used in section 848.
- ⟨ Subtract the width of node *v* from *break\_width* 852 ⟩ Used in section 851.
- ⟨ Suppress expansion of the next token 380 ⟩ Used in section 378.
- ⟨ Swap the subscript and superscript into box *x* 753 ⟩ Used in section 749.
- ⟨ Switch to a larger accent if available and appropriate 751 ⟩ Used in section 749.
- ⟨ Tate to other direction 141 ⟩ Used in section 139.
- ⟨ Tell the user what has run away and try to recover 344 ⟩ Used in section 342.
- ⟨ Terminate the current conditional and skip to `\fi` 521 ⟩ Used in section 378.
- ⟨ Test box register status 516 ⟩ Used in section 512.
- ⟨ Test if an integer is odd 515 ⟩ Used in section 512.
- ⟨ Test if two characters match 517 ⟩ Used in section 512.
- ⟨ Test if two macro texts match 519 ⟩ Used in section 518.
- ⟨ Test if two tokens match 518 ⟩ Used in section 512.
- ⟨ Test relation between integers or dimensions 514 ⟩ Used in section 512.
- ⟨ The KANJI height for *cur\_jfont* 1419 ⟩ Used in section 466.
- ⟨ The KANJI width for *cur\_jfont* 1418 ⟩ Used in section 466.
- ⟨ The em width for *cur\_font* 569 ⟩ Used in section 466.
- ⟨ The x-height for *cur\_font* 570 ⟩ Used in section 466.
- ⟨ Tidy up the parameter just scanned, and tuck it away 411 ⟩ Used in section 403.
- ⟨ Transfer node *p* to the adjustment list 666 ⟩ Used in section 662.
- ⟨ Transplant the post-break list 895 ⟩ Used in section 893.
- ⟨ Transplant the pre-break list 896 ⟩ Used in section 893.
- ⟨ Treat *cur\_chr* as an active character 1164 ⟩ Used in sections 1163 and 1167.
- ⟨ Try the final line break at the end of the paragraph, and **goto done** if the desired breakpoints have been found 884 ⟩ Used in section 874.
- ⟨ Try to allocate within node *p* and its physical successors, and **goto found** if allocation was possible 128 ⟩  
Used in section 126.
- ⟨ Try to break after a discretionary fragment, then **goto done5** 880 ⟩ Used in section 877.
- ⟨ Try to get a different log file name 546 ⟩ Used in section 545.
- ⟨ Try to hyphenate the following word 905 ⟩ Used in section 877.
- ⟨ Try to recover from mismatched `\right` 1204 ⟩ Used in section 1203.
- ⟨ Types in the outer block 18, 25, 39, 102, 110, 114, 156, 218, 275, 306, 559, 605, 931, 936 ⟩ Used in section 4.
- ⟨ Undump MLT<sub>E</sub>X-specific data 1415 ⟩ Used in section 1316.
- ⟨ Undump a couple more things and the closing check word 1340 ⟩ Used in section 1316.
- ⟨ Undump constants for consistency check 1321 ⟩ Used in section 1316.
- ⟨ Undump regions 1 to 6 of *eqtb* 1330 ⟩ Used in section 1327.
- ⟨ Undump the array info for internal font number *k* 1336 ⟩ Used in section 1334.
- ⟨ Undump the dynamic memory 1325 ⟩ Used in section 1316.
- ⟨ Undump the font information 1334 ⟩ Used in section 1316.
- ⟨ Undump the hash table 1332 ⟩ Used in section 1327.
- ⟨ Undump the hyphenation tables 1338 ⟩ Used in section 1316.
- ⟨ Undump the string pool 1323 ⟩ Used in section 1316.
- ⟨ Undump the table of equivalents 1327 ⟩ Used in section 1316.
- ⟨ Undump *xord*, *xchr*, and *xprn* 1401 ⟩ Used in section 1321.
- ⟨ Update the active widths, since the first active node has been deleted 872 ⟩ Used in section 871.
- ⟨ Update the current height and depth measurements with respect to a glue or kern node *p* 987 ⟩  
Used in section 983.
- ⟨ Update the current page measurements with respect to the glue or kern specified by node *p* 1015 ⟩  
Used in section 1008.
- ⟨ Update the value of *printed\_node* for symbolic displays 869 ⟩ Used in section 840.
- ⟨ Update the values of *first\_mark* and *bot\_mark* 1027 ⟩ Used in section 1025.
- ⟨ Update the values of *last\_glue*, *last\_penalty*, and *last\_kern* 1007 ⟩ Used in section 1005.

- ⟨ Update the values of *max\_h* and *max\_v*; but if the page is too large, **goto done** 652 ⟩ Used in section 651.
- ⟨ Update width entry for spanned columns 809 ⟩ Used in section 807.
- ⟨ Use code *c* to distinguish between generalized fractions 1194 ⟩ Used in section 1193.
- ⟨ Use node *p* to update the current height and depth measurements; if this node is not a legal breakpoint, **goto not\_found** or *update\_heights*, otherwise set *pi* to the associated penalty at the break 984 ⟩  
Used in section 983.
- ⟨ Use size fields to allocate font information 577 ⟩ Used in section 573.
- ⟨ Wipe out the whatsit node *p* and **goto done** 1371 ⟩ Used in section 208.
- ⟨ Wrap up the box specified by node *r*, splitting node *p* if called for; set *wait* ← *true* if node *p* holds a remainder after splitting 1032 ⟩ Used in section 1031.
- ⟨ Yoko to other direction 140 ⟩ Used in section 139.
- ⟨ goto *main\_lig\_loop* 1050 ⟩ Used in sections 1049, 1049, 1049, 1049, and 1049.

	Section	Page
Changes to 1.	Introduction . . . . .	1 3
Changes to 2.	The character set . . . . .	17 11
Changes to 3.	Input and output . . . . .	25 14
Changes to 4.	String handling . . . . .	39 20
Changes to 5.	On-line and off-line printing . . . . .	55 25
Changes to 6.	Reporting errors . . . . .	73 32
Changes to 7.	Arithmetic with scaled dimensions . . . . .	100 41
Changes to 8.	Packed data . . . . .	111 45
Changes to 9.	Dynamic memory allocation . . . . .	116 47
Changes to 10.	Data structures for boxes and their friends . . . . .	134 53
Changes to 11.	Memory layout . . . . .	168 62
Changes to 12.	Displaying boxes . . . . .	179 66
Changes to 13.	Destroying boxes . . . . .	205 73
Changes to 14.	Copying boxes . . . . .	209 75
Changes to 15.	The command codes . . . . .	213 77
Changes to 16.	The semantic nest . . . . .	217 82
Changes to 17.	The table of equivalents . . . . .	226 87
Changes to 18.	The hash table . . . . .	262 110
Changes to 19.	Saving and restoring equivalents . . . . .	274 117
Changes to 20.	Token lists . . . . .	295 123
Changes to 21.	Introduction to the syntactic routines . . . . .	303 127
Changes to 22.	Input stacks and states . . . . .	306 129
Changes to 23.	Maintaining the input stacks . . . . .	327 140
Changes to 24.	Getting the next token . . . . .	338 143
Changes to 25.	Expanding the next token . . . . .	374 155
Changes to 26.	Basic scanning subroutines . . . . .	413 166
Changes to 27.	Building token lists . . . . .	475 186
Changes to 28.	Conditional processing . . . . .	498 194
Changes to 29.	File names . . . . .	522 202
Changes to 30.	Font metric data . . . . .	550 215
Changes to 31.	Device-independent file format . . . . .	594 234
Changes to 32.	Shipping pages out . . . . .	603 241
Changes to 33.	Packaging . . . . .	655 262
Changes to 34.	Data structures for math mode . . . . .	691 273
Changes to 35.	Subroutines for math mode . . . . .	710 282
Changes to 36.	Typesetting math formulas . . . . .	730 289
Changes to 37.	Alignment . . . . .	779 309
Changes to 38.	Breaking paragraphs into lines . . . . .	824 327
Changes to 39.	Breaking paragraphs into lines, continued . . . . .	873 345
Changes to 40.	Pre-hyphenation . . . . .	902 357
Changes to 41.	Post-hyphenation . . . . .	911 362
Changes to 42.	Hyphenation . . . . .	930 372
Changes to 43.	Initializing the hyphenation tables . . . . .	953 379
Changes to 44.	Breaking vertical lists into pages . . . . .	978 390
Changes to 45.	The page builder . . . . .	991 396
Changes to 46.	The chief executive . . . . .	1040 414
Changes to 47.	Building boxes and lists . . . . .	1067 426
Changes to 48.	Building math lists . . . . .	1148 453
Changes to 49.	Mode-independent processing . . . . .	1220 473
Changes to 50.	Dumping and undumping the tables . . . . .	1312 495
Changes to 51.	The main program . . . . .	1343 508
Changes to 52.	Debugging . . . . .	1351 515
Changes to 53.	Extensions . . . . .	1353 517
Changes to 54/ <del>System</del> -dependent changes for <del>Web2c</del>	. . . . .	1392 527
Changes to 54/ <del>The</del> existing recycling routines . . . . .	. . . . .	1402 529
Changes to 54/ <del>MLTeX</del> -dependent changes for <del>MLTeX</del>	. . . . .	1404 530
Changes to 55/ <del>System</del> -dependent changes for <del>pTeX</del>	. . . . .	1416 536
Changes to 56.	System-dependent changes . . . . .	1474 556
Changes to 55.	Index . . . . .	1477 557
